WORLD BOOK photo by Alexander Sobelewski

Nonverbal arts communicate without using words. Music is one of the most important of these arts. A musical composition may express emotions or ideas as strongly as a work of literature.

A third group of nonverbal arts, which some experts consider part of the second group, produces *three-dimensional objects* which we can see from several points of view, and also can touch. There is no general name for them, but they include sculpture, architecture, ceramics, weaving, fine glassware, jewelry, and furniture.

Mixed arts are combinations of the basic arts. For example, songs and oratorios consist of music and poetry. Dance is a combination of music and action. Drama combines action, words, and stage scenery. Films combine visual design with storytelling.

Scholars often wonder whether other senses besides sight and hearing might be used for works of art. Should a dinner that is made of gourmet dishes be considered a work of art? Could a series of different odors be considered a work of art?

Enjoying the arts

People who love music, who can lose themselves in a book, or who can spend hours painting a picture of a barn know the deep satisfaction that can be found in art. It is not easy to express this satisfaction in words. But, in some partly mysterious way, works of art are among the things of highest value in our lives.

A fine piece of music, a masterpiece of painting, or a first-rate play has the power to capture and hold our fullest and most concentrated attention. We are completely wrapped up in it, and everything works out right. The music comes to the right close at the right time and in the right way. The play ends, not necessarily on a happy note, but in a way that seems inevitable and appropriate. As we grow more and more aware of the painting, its parts seem to belong together and to be made for each other. We perceive harmony in the object and feel harmony within ourselves.

When the aesthetic experience has ended, we often feel uplifted and refreshed. Our eyes and ears, our insight into other persons, or our understanding of moral values may be sharpened and refined. We may feel more at home with ourselves. Works of art have value for us in some such ways as these.

It is this value that marks the difference between great art and simple entertainment. A work that is fairly easy to understand and appreciate takes little effort on our part. It may give us pleasure. But it does not involve our emotions or our attention at a deep level. It may take our minds off our troubles for a time, but it does not give us the spiritually enriching experience of vital and orderly design.

Studying the arts

To enjoy the special value of works of art, we must be ready to give a great deal to them. The greatest works of music and poetry often present difficulties. We cannot expect to master them all at once. And we cannot always find what is worthy in them at a glance. It is possible to get some satisfaction out of music while reading a newspaper or peeling potatoes. But we must listen with full attention before we can find the riches in great works of music.

Some of us feel that we cannot find much to enjoy in one art or another. But most of us can find aesthetic satisfaction in some of the arts—if we know how to go about it. In addition, many of us find that music, painting, or poetry provides an inexhaustible source of joy.

At the same time, we may discover that we ourselves have the ability to create art. If we do, we have a source of satisfaction we do not want to miss. Children take music lessons, learn to sing together, and study drawing. Many persons try amateur acting, or write stories and poems. Some have great talent and become professional artists. Even those of us who conclude that we do not have much creative ability find that trying to paint or write sharpens our perceptions and adds to our enjoyment of the arts.

There is also a more theoretical approach to the arts. We may begin to think about some of the more complex matters connected with appreciating artworks. This is the study of aesthetics. It tries to find what makes one work of art better than another, and whether there are objective standards of criticism. It considers how our interest in art is connected with our other great philosophic interests such as science and religion. Philosophers have studied such questions. In asking and trying to answer them, we become philosophers ourselves.

Art deco was a style of design that became popular during the 1920's and 1930's. It was used chiefly in furniture, jewelry, pottery, and textiles. Most art deco designers created objects that could be mass-produced, rather than such individual works as paintings and sculptures. The term *art deco* comes from *Exposition Internationale des Arts Décoratifs et Industriels Modernes,* the title of a design exhibition held in Paris in 1925.

Mahogany cabinet with kingwood veneer and ivory inlay (about 1923) by Emile-Jacques Ruhlmann; Brooklyn Museum

Art deco furniture, such as the cabinet shown here, has a look of sleek elegance that was characteristic of the style.

Art deco was characterized by geometric shapes, smooth lines, and streamlined forms. It featured a look of sleek elegance that was associated with wealth and sophistication. Many art deco works were made of chrome, plastics, and other industrial materials. Art deco designers also used such expensive materials as crystal, ivory, and silver. The style was inspired by a variety of sources, including cubism and the art of ancient America.

Art deco also influenced architecture. Many buildings in New York City have the metal ornamentation and geometric patterns typical of the style. One such structure is the Chrysler Building, with its soaring tower formed by bands of stainless steel arches. Radio City Music Hall's curving stairways and round chandeliers also show the influence of art deco. Alison McNeil Kettering

Art Institute of Chicago is a museum of art and a cultural and educational center. Collections displayed at the Art Institute include paintings and sculpture; prints and drawings; European and American decorative arts; Asian and classical art; photography; textiles; and the arts and crafts of Africa, Latin America, the Pacific Islands, and pre-Columbian America.

The European painting collection, with examples from the 1300's to the present, is best known for its works by French impressionists and postimpressionists. The large collection of prints at the Art Institute contains unique examples by masters of the 1400's and important series by French artists of the 1800's. The Asian galleries show arts of the Far East, with notable collections of bronzes, sculpture, and Japanese prints. Furniture, glass, porcelain, and metalwork are displayed in the galleries of the museum's Department of European Decorative Arts and Sculpture in the Rice Building. The building is also the location of one of the largest, most comprehensive collections of American art from the late 1600's to the present.

The Art Institute was founded in 1866 as the Chicago Academy of Design. In 1882, it was incorporated under its present name. It is governed by a board of trustees and supported mainly by private funds. The School of the Art Institute grants degrees in the visual and related arts. Art nouveau, *noo VOH,* was a decorative style of design that flourished from the 1890's until about 1910. *Art nouveau* means *new art* in French. It comes from the name of a Paris art gallery, *Maison de l'Art Nouveau,* which exhibited works created in this style of design.

Art nouveau was an ornate style, characterized by long, flowing lines and wavelike contours often influenced by forms in nature. The style developed in part as

Enamel paintings on crystal vases (about 1896) by Alphonse Mucha; Fly By Nite Gallery, Chicago (WORLD BOOK photo)

Art nouveau is characterized by long, flowing lines that twist in snakelike fashion. The images on the vases shown here were painted in this style, which was popular about 1900.

a protest against the mass production of the industrial age. It was used mainly for interior decoration and in the design of glassware, jewelry, and other ornamental objects. Some artists used the art nouveau style for such graphic-design works as book illustrations and posters.

The drawings of the English artist Aubrey Beardsley and the posters of Henri de Toulouse-Lautrec of France are outstanding examples of art nouveau graphic design. Other leading figures in the art nouveau movement included Emile Gallé of France and Louis Comfort Tiffany of the United States, both of whom created colorful glassware. Such architects as Antonio Gaudí of Spain and Victor Horta of Belgium also incorporated elements of the style in their work. Alison McNeil Kettering

Artemis, *AHR tuh mihs,* was a goddess in Greek mythology. She was the daughter of Zeus, the king of the gods, and the goddess Leto. The god Apollo was her twin. Artemis was sometimes identified with the moon goddess Selene. The Roman fertility goddess Diana closely resembled her.

Artemis was the goddess of childbirth and female maturation. Young girls about to be married prayed to her and sometimes dedicated their dolls or a lock of hair to her. But Artemis could be cruel and destructive. She and Apollo killed the children of Niobe, queen of Thebes, after Niobe boasted that she had more children than Leto. The Greeks often blamed Artemis for the sudden death of women.

Artemis was a virgin goddess who demanded that her followers dedicate themselves to lives of purity. According to one myth, Artemis shot one of her followers, the nymph Callisto, with an arrow after Callisto became pregnant by Zeus. Other sources say she transformed her into a bear. Several myths tell of attempts to rape Artemis and of her successful defense.

Artemis was the goddess of wild animals and hunting. Artists showed her as a beautiful young huntress carrying a bow and a quiver of arrows, often with a deer at her side. Nancy Felson

Arteriosclerosis, *ahr TIHR ee oh skluh ROH sihs,* is a disease of the arteries. It is often called "hardening of the arteries" because it involves hardening, thickening, and loss of elasticity in the artery walls.

There are several forms of arteriosclerosis. Two types are *Mönckeberg's arteriosclerosis,* in which the middle layer of the arteries becomes stiffened by calcium deposits, and *arteriolar sclerosis,* which affects the body's smaller arteries. But by far the most widespread form of arteriosclerosis is the type called *atherosclerosis.* Atherosclerosis affects medium and large arteries, especially those that carry blood to the heart, brain, kidneys, and legs. The effects of the disease appear mainly in middle-aged or older people, but they may also strike young people. Atherosclerosis ranks as a major health problem in the United States and other developed countries. The remainder of this article discusses atherosclerosis.

Causes. Atherosclerosis begins when certain fatty substances in the bloodstream—particularly cholesterol—form deposits on the inner lining of the arteries. Over a period of years, these deposits, called *fatty streaks,* enlarge and thicken to form *plaques.* The plaques have rough edges that irritate the smooth lining of the arteries, causing cells to die and scars to form. The build-up of dead cells, calcium, and scar tissue in the plaques makes the arteries hard and narrow, decreasing the flow of blood. The rough surface of the arteries may cause a *thrombus* (blood clot) to form on the arterial wall. A thrombus can block an artery suddenly.

Certain risk factors are associated with the development of atherosclerosis. Three major risk factors are *hypertension* (high blood pressure), cigarette smoking, and high blood levels of cholesterol. Others include obesity, physical inactivity, and diabetes mellitus.

Effects of atherosclerosis result from the decreased flow of blood through the diseased arteries. Tissues nourished by these arteries do not receive enough oxygen. A decrease in the blood supply to the brain can cause dizziness, numbness, slurred speech, and other symptoms. In the heart, decreased blood supply can produce severe chest pain called *angina pectoris.* The complete blockage of an artery supplying the heart or the brain results in a heart attack or a stroke, respectively. A reduced flow of blood to the kidneys may cause hypertension or kidney damage. In the legs, it may cause pain while walking, skin sores, or *gangrene* (death of tissue).

Prevention and treatment. Most physicians believe that many cases of atherosclerosis can be prevented by reducing exposure to risk factors. Therefore, doctors advise people to avoid cigarette smoking, to reduce if overweight, and to exercise regularly. Detection and control of hypertension and diabetes mellitus are especially important. Many physicians also recommend a diet low in cholesterol and saturated fats.

Treatment of atherosclerosis, like prevention, centers on reducing risk factors. Some patients also get drugs that lower the blood levels of cholesterol. If a major artery becomes obstructed, surgery may be needed. In severe cases, diseased arteries may be replaced or bypassed by grafts of natural or artificial vessels. Another technique, called *angioplasty,* involves threading a balloon-tipped *catheter* (slender tube) into the blocked artery. The balloon is then inflated, flattening the blockage against the artery wall. Toby R. Engel

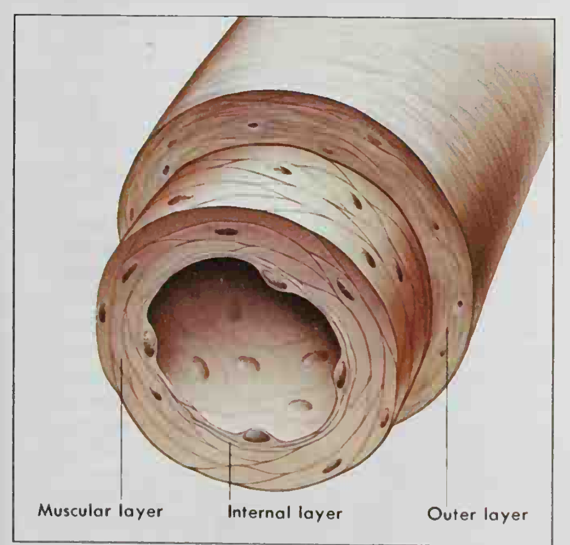
Artery, *AHR tuhr ee,* is the name of the tubes or blood vessels through which blood is pumped away from the heart to the various parts of the body. The blood carried by most arteries is bright red because it has picked up oxygen while passing through the lungs. However, the blood that flows through the arteries connecting the right side of the heart with the lungs has not yet picked up oxygen. This blood has a brownish color. If an artery is cut, blood gushes out in spurts timed with the heartbeats. Veins differ from arteries because they carry the blood back to the heart instead of away from the heart. If a vein is cut, blood flows from it in an even stream.



When a large blood vessel has been cut by accident, the difference in the color and flow of the blood from

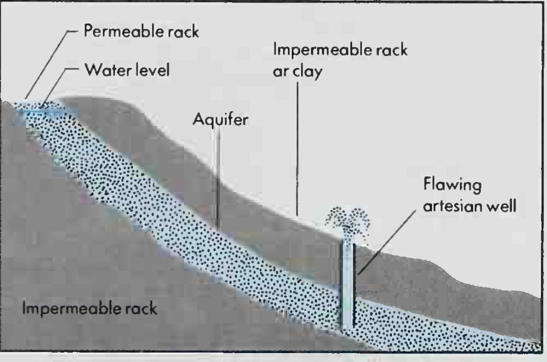
the vessel makes it possible to tell whether an artery or a vein has been injured.

The walls of arteries are made up of three layers. The outer layer consists of elastic tissue, and the middle layer is muscle. The inner layer, or lining, of the arteries is made of thin, smooth cells of the same kind that line the other blood vessels and the heart. Each time the heart beats, the elastic walls of the arteries swell to make room for the blood forced into them. Then their muscular tissues slowly contract again. This squeezes the blood farther along the length of the arteries and toward the capillaries. In this way, the arteries do a considerable share of the work that keeps the blood circulating through the body. If the arteries had rigid instead of elastic walls, the heart would have to pump all the blood without the arteries' assistance. As a result, the heart would work much harder than it does. This is what happens to persons who suffer from *arteriosclerosis* (hardening of the arteries).

Principal arteries. The largest of all the arteries is the *aorta.* It is directly connected with a chamber of the heart. The heart pumps oxygenated blood through the aorta and its many branches to nearly all parts of the body. Two small but important branches of the aorta are the *coronary* arteries. They supply the blood by which the heart muscle itself is nourished. The right and left *carotid* arteries carry blood to the two sides of the head and neck. Blood flows through the right and left *subclavian* arteries to the shoulders and arms. Numerous other branches of the aorta furnish blood to the internal organs. In the abdominal region the aorta divides into two large branches, the right and left *iliac* arteries. These arteries have branches that supply the organs located in the pelvis. The iliac arteries then continue downward into the legs, where they become known as the *femoral* arteries.

After the arterial blood has passed through the body and has picked up impurities, the veins collect it and return it to another chamber of the heart. The heart pumps this blood through the *pulmonary* artery to the lungs.

WORLD BOOK illustration by Robert Demarest



Cross section of an artery

Here the blood takes on a new store of oxygen. It then returns to the heart, where it is once more pumped out through the aorta. Joseph V. Simone

Artesian well, *ahr TEE zhuhn,* is a well that taps ground water which is under pressure. Such water can rise to the surface without the aid of a pump if enough pressure exists. The term *artesian well* also refers to any extremely deep water well.

Most artesian wells tap a layer of porous material filled with ground water. This layer, called an *aquifer,* may lie between two layers of clay or some other material that does not let water through. The aquifer may be tilted, allowing rainfall to refill it at its upper end. This water seeps down in the aquifer, supplying the reservoir of ground water. An artesian well flows naturally because of the pressure exerted on water in the aquifer

WORLD BOOK diagram by Zorica Dabich

An artesian well, as shown in this cross-section drawing, taps a layer of permeable rock filled with ground water. This *aquifer,* which lies between layers of impermeable material, is refilled from the rainfall at its upper end. Pressure exerted by the inflowing water causes the water in the aquifer to rise.

by water entering at the aquifer's upper end.

Areas where artesian wells can be drilled are called *artesian basins.* The word *artesian* comes from *Artois,* a province in France, where artesian wells were first drilled during the 1100's. Douglas S. Cherkauer

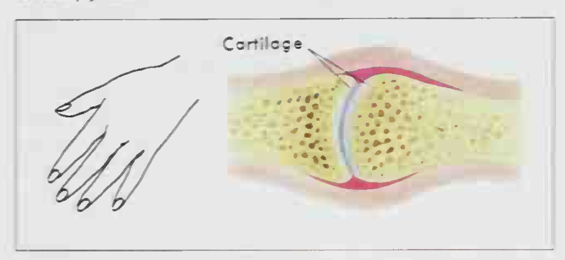
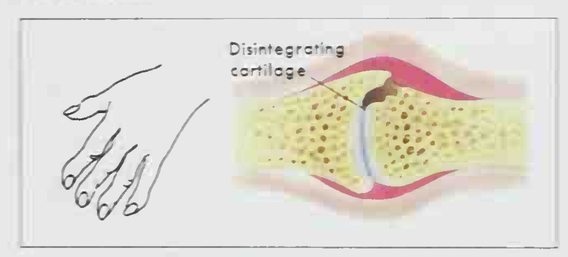
Arthritis, *ahr THRY tihs,* is any of more than 100 diseases of the joints. Victims of arthritis suffer pain, stiffness, and swelling in their joints. Many people are crippled by arthritis. In the United States, more than 31 million people of all ages and backgrounds suffer from the disease.



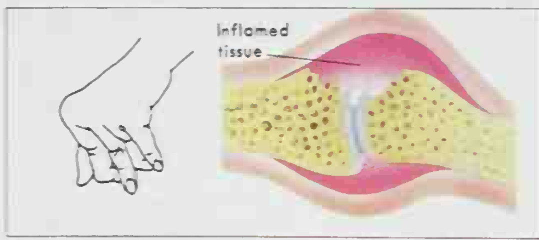
The terms *arthritis* and *rheumatism* are often used interchangeably. However, rheumatism is a more general term that refers to a variety of disorders of the joints, muscles, and connecting tissues. The two chief forms of arthritis are *osteoarthritis* and *rheumatoid arthritis.*

Osteoarthritis, also called *degenerative joint disease,* occurs when a joint wears out. Many elderly people have osteoarthritis, and the disease may also occur if a joint has been injured many times. The joints most frequently affected are those of the hands, hips, knees, lower back, and neck. Severe disability may result, espe-



The two main types of arthritis

Many forms of arthritis can disable the joints. In a healthy joint, cartilage covers the ends of the bones. In *osteoarthritis,* the cartilage disintegrates and the bones rub against one another. In *rheumatoid arthritis,* inflamed tissue in a joint leads to erosion of the cartilage and the bones. Joints affected by severe cases of rheumatoid arthritis may stiffen in deformed positions.



Healthy joints

Osteoarthritis

Rheumatoid arthritis

WORLD BOOK illustrations by Charles Wellek

cially if the hips or knees are badly diseased.

Patients with osteoarthritis suffer pain in the afflicted area and may feel a grating sensation when they move. In osteoarthritis, the cartilage between bones breaks down, causing those bones to rub against each other. Knobs of bone and of hardened bits of cartilage may develop in the joint, causing swelling and deformity.

Physicians treat patients to relieve pain and prevent disability from osteoarthritis. Treatment includes drugs and special programs of exercise. Surgeons may repair or replace some severely damaged joints. Because osteoarthritis affects millions of people, seeking new treatments is an active area of medical research. A new class of drugs called *Cox-2 inhibitors,* developed in 1999, relieves the pain and inflammation of osteoarthritis with fewer side effects than aspirin and other drugs.

Rheumatoid arthritis is often called the "great crippler." Most of its victims are between the ages of 20 and 40, but it can strike children or elderly people.

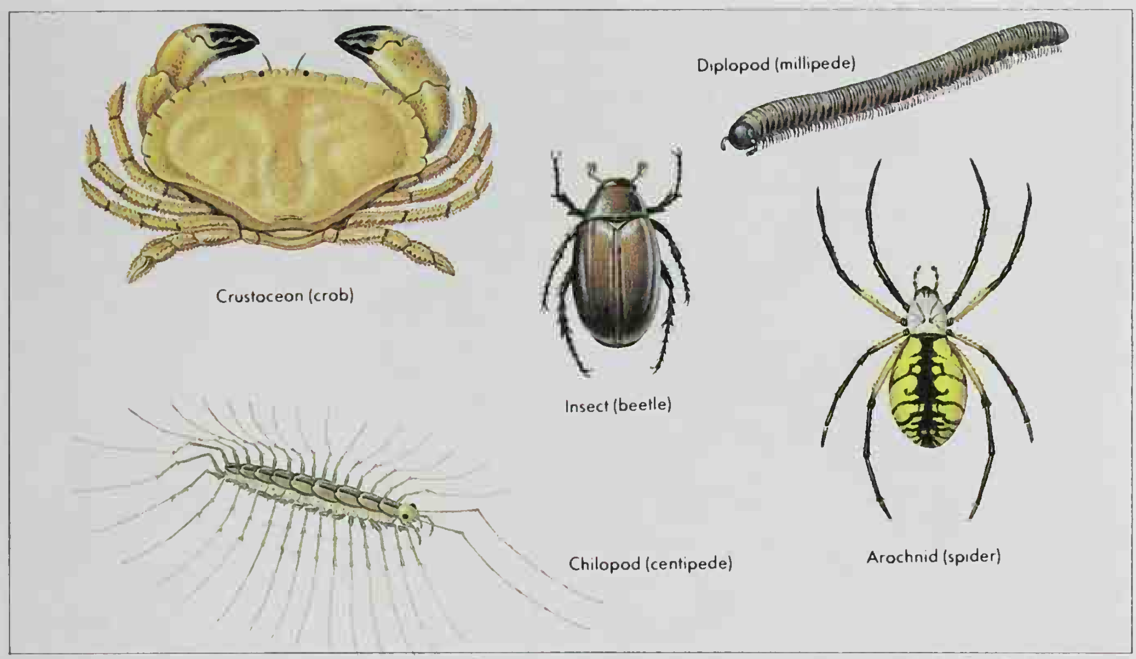
Joints afflicted by rheumatoid arthritis are hot, painful, red, and swollen. The disorder affects chiefly the wrists and knuckles, but it may occur in any joint. In many cases, rheumatoid arthritis spreads throughout the body, damaging organs and connective tissue. If it remains unchecked, the diseased joints eventually stiffen in deformed positions. The disorder may remain throughout the patient's life or disappear for varying periods of time.

In rheumatoid arthritis, inflamed tissue and other substances in a joint erode the bone and cartilage. Physicians believe the disease is caused by either microorganisms or *autoimmunity* (the body's attack on its own tissues), or both (see **Immune system**). Some people inherit a tendency toward rheumatoid arthritis.

Doctors try to prevent the disease from disabling its victims. Treatment includes rest, a program of exercises, and aspirin, Cox-2 inhibitors, or other drugs. In extremely severe cases, doctors may give injections of a gold compound or prescribe powerful medications, such as methotrexate. A badly damaged joint can be repaired or replaced.

Other forms of arthritis include *gout, ankylosing spondylitis,* and *septic arthritis.* Gout victims suffer repeated flare-ups of painful swelling, but they feel well between attacks. The bunion joint, which connects the big toe and the foot, is affected first in most cases. Gout is caused by the presence of too much uric acid in the blood. During an attack, this chemical takes the form of needle-shaped crystals in the joints. Some people inherit gout. Alcoholic beverages and rich food can lead to an attack in people who have gout, but they do not cause the disease. Doctors prescribe drugs to reduce inflammation and prevent further attacks. See **Gout**.

Ankylosing spondylitis attacks chiefly young men. The spinal joints become inflamed, and the patient develops a rigid, stooped back. Most victims of the disease have a rare blood type called HLA B-27. Treatment consists of physical therapy and drugs.



Septic arthritis is infection of a joint by bacteria. Its most common forms occur after a lung or skin infection, surgery on the joint, or any of several sexually transmitted diseases. In most cases, early treatment with antibiotic drugs prevents crippling. Michael D. Lockshin

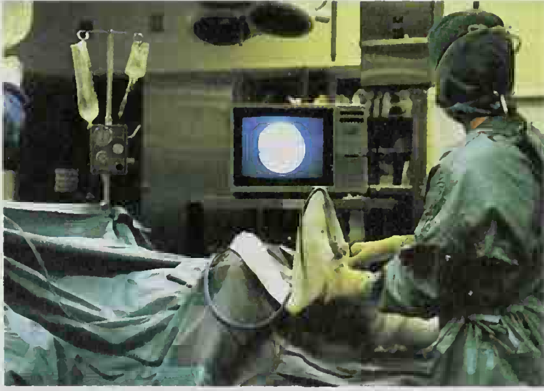
Arthropod, *AHR thruh pahd,* is any animal that belongs to the major division, or *phylum,* of the animal kingdom called the *Arthropoda.* This term is formed from two Greek words, and means *jointed feet.* Actually, the legs, rather than the feet, are jointed. All the Arthropoda, or arthropods, have jointed legs. Among the most important groups of arthropods are the following: (1) insects, including cockroaches, beetles, bees, butterflies, and many others; (2) crustaceans, including such well-known animals as crabs, lobsters, shrimps, and barnacles; (3) arachnids, including mites, ticks, spiders, and scorpions; (4) chilopods, or centipedes; and (5) diplopods, or millipedes. The arthropod phylum contains more than three-fourths of all the different kinds of animals. Insects make up the largest class of arthropods

WORLD BOOK illustrations by James Teason

Arthropods form a major division of the animal kingdom. All of these animals have jointed legs. Examples of some of the most important groups of arthropods are shown above.



in terms of the number of species.

The bodies of arthropods, as well as their legs, are made up of sections. Among some primitive arthropods, each section of the body has its own pair of legs. Most of these legs are used for swimming or walking. In some types of arthropods, certain legs have developed special shapes and uses. Some serve as sucking organs, some are jaws, some serve as weapons of offense and defense, and some are sense organs. Insects lack most of the pairs of legs found in other arthropods. They have only three pair. One pair is attached to each segment of an insect's chest or thorax. Insects also may have one or two pairs of wings.

Arthropods have an outside shell, or *exoskeleton,* that contains a stiff, horny material called *chitin.* Certain arthropods, such as flies and moths, have only thin, weak shells. Others, including crabs and lobsters, have thick, strong shells. Nearly all arthropods have a kind of heart and blood system and usually a well-organized nervous system. Some arthropods have simple eyes, some have compound eyes, and some (including many insects) have eyes of both types. Sandra J. Glover

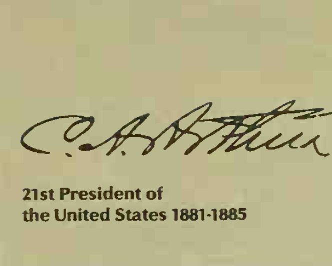
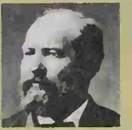
Arthroscopy, *ahr THRAHS kuh pee,* is the technique of using an *arthroscope* to examine a joint of the body. An arthroscope is a straight, tubelike instrument with a series of lenses and optical-fiber bundles. It comes in sizes from $\frac{1}{12}$ to $\frac{1}{5}$ inch (2 to 5 millimeters) in diameter. It can be inserted into a joint through a small incision. A light transmitted by the optical fibers to the tip of the arthroscope illuminates the joint. Using an arthroscope, a doctor can thoroughly examine a joint and perform certain surgical operations.

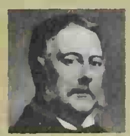


Preston M. Wolin, M.D., Rush-Presbyterian-St. Luke's Medical Center, Chicago



Arthroscopy allows a physician to examine and treat joint problems. In the picture above, the tubelike arthroscope has been inserted into a patient's knee joint.

Doctors use arthroscopy mainly on shoulder, elbow, hip, and knee joints. The problem most commonly treated by arthroscopy is torn cartilage in the knee. The doctor diagnoses this problem by looking into the knee joint through the arthroscope. Then the cartilage is removed with other instruments through a second incision.



The main advantage of arthroscopic surgery is that the operation can be performed through a small incision at the joint. As a result, a patient can sometimes have the surgery and leave the hospital the same day. Also, the patient experiences a minimum amount of discomfort, and healing time is much shorter than for other methods of surgery. James A. Hill

21st President of the United States 1881-1885

Garfield
20th President

Cleveland
22nd President
1885-1889
Democrat

Oil painting on canvas (1884) by G.P.A. Healey, Corcoran Gallery of Art, Washington, D.C., gift of William Willson Corcoran

Arthur, Chester Alan (1829-1886), became President after James A. Garfield died from an assassin's bullet. Arthur was the fourth Vice President to succeed to the presidency upon the death of a chief executive.

Arthur had risen rapidly in the Republican Party *machine* (organization) of New York City. In 1871, he became collector of the New York Custom House, then the largest single federal office in the United States. Widespread dishonesty in government occurred during this period, and Arthur used his office to reward Republicans and strengthen the party. These actions contributed to graft and waste in the custom house and led to his removal in 1878.

As President, however, Arthur surprised the nation by the honesty and efficiency shown by his Administration. Protests by reformers about the dishonesty of previous administrations in the appointment of government officials caused Congress to pass the Civil Service Act. Arthur signed the law and administered it faithfully.

Arthur enjoyed fashionable surroundings and fine clothes. He also liked to entertain friends. Tall, ruddy, and handsome, Arthur was sometimes called the "Gentleman Boss." He traveled widely as President, attending the opening of the Brooklyn Bridge in New York City and touring Florida and Yellowstone National Park.

Important dates in Arthur's life

1829 (Oct. 5) Born in Fairfield, Vt.
1859 (Oct. 25) Married Ellen Lewis Herndon.
1871 Named collector of the New York Custom House.
1880 (Jan. 12) Mrs. Ellen Arthur died.
Elected Vice President of the United States.
1881 (Sept. 20) Sworn in as President.
1886 (Nov. 18) Died in New York City.

While Arthur was President, the United States celebrated the 100th anniversary of the British surrender at Yorktown. New books included *The Adventures of Huckleberry Finn* and *Life on the Mississippi* by Mark Twain. Cities and towns throughout the United States and Canada began to adopt standard time after the railroads devised time zones to aid travelers.

Early life

Boyhood. Chester Alan Arthur was born on Oct. 5, 1829, in Fairfield, Vt. He was the first son in a family of six girls and three boys. His father, William, had come to the United States from Northern Ireland. The elder Arthur was a teacher and Baptist minister. Chester's mother, Malvina Stone Arthur, grew up on her father's Vermont farm. Like many other rural ministers, William Arthur seldom stayed long at any one post. The family moved to various villages in Vermont and upstate New York.

Chester was a good student and developed an early interest in politics. In 1844, at the age of 14, he supported Henry Clay, the Whig Party's presidential candidate, and got into a fight with some young opponents of Clay. "I have been in many a political battle since then," Arthur later recalled, "but none livelier, or that more thoroughly enlisted me."

Legal career. At the age of 18, Arthur graduated from Union College in Schenectady, N.Y. He began studying law and at the same time taught school. In 1854, he became a partner in a New York City law firm. Arthur soon became known as a defender of the civil rights of blacks. The young lawyer won a case in 1855 that established the right of blacks to ride on any streetcar in New York City.

Marvels of engineering were erected in the 1880's. The Brooklyn Bridge, *above,* was the world's longest suspension bridge when it opened in 1883. The Home Insurance Building in Chicago, *left,* was the first metal-frame skyscraper. The structure was built in 1884 and 1885.

The world of President Arthur

Trade unionists led by Samuel Gompers founded the Federation of Organized Trades and Labor Unions of the United States and Canada in November 1881. The group later reorganized as the American Federation of Labor.
The Standard Oil Trust was formed in 1882 by John D. Rockefeller and his associates in the oil industry. The trust controlled about 90 per cent of the oil refining capacity in the United States until it was forced to disband in 1892.
The germ that causes tuberculosis was discovered by German physician Robert Koch in 1882.
Jesse James, a notorious bank and train robber, was killed by one of his own gang members, Robert Ford, in 1882. Ford shot James in order to receive a $5,000 reward.
Popular entertainment took various forms in the early 1880's. In 1883, William Frederick Cody, known as Buffalo Bill, organized his "Wild West Circus" to tour the United States and Europe. That same year, the first vaudeville theater in the United States opened in Boston, and the Metropolitan Opera House opened in New York City.
Standard time was adopted by the railroads in 1883. The four time zones in the United States replaced about 100 different "railroad times."
The linotype machine was patented by German-born inventor Ottmar Mergenthaler in 1884. The machine greatly increased the speed of typesetting.
The Adventures of Huckleberry Finn by Mark Twain was published in England in 1884 and in the United States in 1885. The novel became known as an American masterpiece.

Leslie's Illustrated Weekly, Newberry Library, Chicago; Brown Brothers

Arthur's family. On Oct. 25, 1859, Arthur married Ellen Lewis Herndon (Aug. 30, 1837-Jan. 12, 1880), the daughter of a naval officer. The couple had two sons and a daughter, but the older boy died at the age of 2½. Mrs. Arthur died a year before Arthur became Vice President, leaving him with their children, Chester, Jr., and Ellen.

Political and public career

Political growth. In 1854, Arthur attended a meeting that led to the creation of a Republican Party in New York. Edwin D. Morgan, a Republican, became governor of New York in 1859, and Republican friends of Arthur's got him a position on Morgan's staff. Morgan soon named Arthur state engineer-in-chief with the rank of brigadier general. After the Civil War began in 1861, Morgan put Arthur in charge of outfitting the New York militia for federal service. The governor appointed Arthur inspector general of the militia early in 1862 and later that year appointed him state quartermaster-general.

Custom house collector. During the late 1860's, Arthur became an associate of Senator Roscoe Conkling of New York. Conkling was the leader of the New York Republican organization. To help this machine, President Ulysses S. Grant in 1871 appointed Arthur collector of the New York Custom House. The custom house, with more than 1,000 employees, was then the largest federal office in the nation. Officially, Arthur supervised the collection of import duties. But politically, he used the position to strengthen the Republican Party, largely by giving jobs to party workers.

Arthur soon became the leader of the party machine in New York City, and eventually became chairman of the Republican state committee. All the customs employees paid a portion of their salaries into Republican campaign funds. Some money collected for customs violations also ended up in the treasury of the Republican Party. Politicians in all parts of the country took similar advantage of this so-called spoils system (see **Spoils system**). Reformers protested that such appointments resulted in incompetent and dishonest officials. After Rutherford B. Hayes became President of the United States in 1877, he issued an order forbidding government employees from taking part in the management of a political party.

Vermont Division of Historic Preservation

A replica of Arthur's birthplace stands in Fairfield, Vt. The state maintains the house and a small park as a memorial.

Library of Congress; © White House Historical Association (National Geographic Society)

Ellen Herndon Arthur, *above,* died the year before her husband became President. Arthur's youngest sister, Mary Arthur McElroy, *right,* was his White House hostess.

Hayes appointed a commission to investigate the New York Custom House. The commission uncovered evidence of corruption, inefficiency, and waste. It also found continued involvement by the top custom house officials in Republican Party affairs. In 1877, Hayes asked Arthur and two chief aides to resign. They replied that they would not give up their offices until, as then required by law, the Senate had confirmed new appointees. Hayes suspended Arthur and one of the aides in 1878. Senator Conkling temporarily blocked the confirmation of new appointees. The Senate approved the new officials early in 1879.

Election of 1880. At the Republican National Convention of 1880, Conkling's machine supported former President Grant for a third term. However, the convention nominated Senator-elect James A. Garfield of Ohio. The delegates then nominated Arthur for Vice President in hope of receiving support from Grant's followers. Garfield and Arthur defeated their Democratic opponents, General Winfield Scott Hancock and former Congressman William H. English of Indiana (see **Garfield, James A.** [Election of 1880]).

Opposition to Garfield. Arthur soon found himself in the middle of a quarrel between President Garfield and Senator Conkling. Conkling demanded that Garfield consult him on all federal appointments in New York. He became furious when Garfield named James G. Blaine, Conkling's chief political enemy, as secretary of state and another old political opponent as collector of the New York Custom House.

Conkling and Thomas C. Platt, the other New York senator, both resigned. They asked the New York Legislature to show its disapproval of Garfield by reelecting them to the Senate. Arthur shocked many political observers by campaigning for his friends, but they were defeated.

Assassination of Garfield. Garfield never had a chance to enjoy the benefits of his victory over Senator Conkling. He was shot by Charles J. Guiteau on July 2, 1881, and died on September 19. Arthur took the presidential oath in his home in New York City at 2:15 a.m. the next day.

Arthur's Administration (1881-1885)

Life in the White House. Arthur thought the White House looked like "a badly kept barracks," and ordered it renovated. During his first months as President, he lived in the Washington home of Senator John P. Jones of Nevada. Arthur moved into the redecorated White House on Dec. 7, 1881. The President, whose wife had died in 1880, asked his youngest sister, Mrs. Mary A. McElroy, to serve as his hostess. She won wide praise for her warm hospitality.

About a year after Arthur became President, he learned that he was dying of a kidney disease called *glomerulonephritis,* or *Bright's disease.* Arthur often suffered great pain but kept his illness a secret.

Civil service reform. Most Americans regarded Arthur as a machine politician. They believed he would oppose civil service reform. But the assassination of Garfield led to a great popular demand for a better system of filling public offices. In response to this demand, Congress passed the Pendleton Civil Service Act. Arthur signed the bill on Jan. 16, 1883. He named attorney Dorman B. Eaton, the author of the bill, as chairman of the first Civil Service Commission. See **Civil service** (History).

The star route frauds. During Garfield's term, two of Arthur's close political allies had been charged with fraud. They were accused of obtaining money by giving false estimates on the cost of operating postal star routes. Arthur renewed the prosecutions, and his Administration worked vigorously for convictions. A jury acquitted the accused men after two trials. But the postal frauds were halted.

The fight for lower tariffs. American consumers exerted pressure on the Arthur Administration to lower

import tariffs. In 1882, the president appointed a commission to study tariff rates. It urged sharp tariff cuts, but Congress ignored the commission and passed a law in 1883 that lowered rates only slightly.

Other legislation. In 1882, Congress authorized $18,743,875 to be spent on improvements for waterways. Arthur knew many of the improvements were extravagant, and he vetoed the bill. But Congress passed the bill over Arthur's veto.

The Edmunds Anti-Polygamy Act of 1882, aimed at the Mormons of Utah, made it illegal for a man to have more than one wife. Congress also passed a bill in 1882 to prohibit Chinese immigration for 20 years. Arthur vetoed the bill, saying it violated a treaty with China. Congress amended the bill to limit the suspension of Chinese immigration to 10 years, and it became law. Arthur also fought with some success to modernize the United States Navy.

Election of 1884. Arthur worked hard to avoid major involvement in Republican Party affairs during his presidency. But in 1882, he was blamed for the defeat of Charles J. Folger, his secretary of the treasury, in the race for governor of New York. Folger lost to Democrat Grover Cleveland. High-ranking Republicans in the Arthur administration tried to build Republican strength in the South but achieved little.

Because of his illness, Arthur quietly discouraged friends from working to help him win the Republican presidential nomination in 1884. He received about a third of the votes for the nomination at the Republican National Convention in Chicago. Former Secretary of State James G. Blaine won the nomination, but he lost the presidential election to Cleveland.

Later years

Arthur returned to New York City after leaving the presidency. His health steadily declined, and he died of a cerebral hemorrhage on Nov. 18, 1886. Arthur was buried beside his wife in the Rural Cemetery at Albany, New York. Thomas C. Reeves

Arthur, King, was a legendary king of medieval Britain. He became the main character in some of the most popular stories in world literature. For almost 1,000 years, writers have told of Arthur's brave deeds and the adventures of his knights of the Round Table.

A real Arthur probably existed, but historians know little about him. Storytellers passed on the earliest tales about Arthur by word of mouth. These storytellers may have based the tales on an actual British leader who won minor victories over German invaders in the early A.D. 500's.

The earliest accounts of Arthur were from Celtic, Latin, and French sources. In Latin sources, Arthur's father was King Uther Pendragon, who fell in love with Igrayne, the wife of the Duke of Cornwall. With the aid of Merlin, a Celtic magician, Uther took the form of the duke and so conceived Arthur. Arthur was raised without knowledge of his royal ancestry. But when he pulled the magic sword Excalibur from a block of stone, he proved himself the rightful heir to the throne of Britain and became king. Later, Arthur married Princess Guenevere. Arthur had several residences. His favorite was Camelot, a castle in southern England.

There are two versions of the events that led to Arthur's death. Both say he fought a war against the Roman emperor Lucius and conquered much of western Europe. Latin chronicles said he was called home before completing his conquest. He had heard that Modred, a knight who was either his nephew or his son, had seized his kingdom and queen. Arthur killed Modred but died from wounds received in the fight.

Later authors wrote that Arthur had completed his victory over the Romans. After he returned to Britain, Arthur and his court began the quest for the Holy Grail, sometimes depicted as the cup or dish that Jesus used at the Last Supper. After the quest ended, a love affair developed between Queen Guenevere and Sir Lancelot, the greatest knight of the Round Table. While fighting a war of revenge against Lancelot, Arthur learned of Modred's treachery. Then followed the battle that resulted in the death of Arthur and Modred. Many people believed that Arthur had gone to the otherworldly island of Avalon to be healed and that someday he would return to help his country.

Sir Thomas Malory compiled his famous prose romance *Le Morte Darthur* (about 1470) from much earlier French and English romances about Arthur. Many authors have based their novels or poems on Malory's work. Edmund Reiss

The artichoke has prickly leaves and an edible bud.

Artichoke is a large, thistlelike plant that produces edible flower buds. The scales and *hearts* (centers) of the buds are eaten as vegetables. Artichokes provide a number of vitamins and minerals. Artichokes are sometimes called *globe artichokes.* They originated in the Mediterranean region. In the United States, artichokes are grown commercially chiefly in California.

Artichoke plants stand 3 to 5 feet (0.9 to 1.5 meters) tall and may spread over an area 5 to 6 feet (1.5 to 1.8 meters) in diameter. In the spring, the *crown* (top of the root) sprouts stems surrounded by large, coarse leaves. Round or oblong buds develop at the tips of the stems and branches. The buds are immature flowers and may range from light- to dark-green and may have a red or purple tint. Buds weigh up to 1 pound (0.45 kilogram).

Artichokes thrive in frost-free climates with cool, foggy summers. Commercial growers usually start artichokes from shoots, though the plants can grow from seeds. Artichoke plants may live more than 15 years. However, commercial growers usually replant their fields every three or four years to ensure strong, active growth. The buds are harvested before they mature. Some harvesting takes place in late summer and into the fall, but most of it is carried out the following spring.

A plant called *Jerusalem artichoke* is related to the sunflower and is not a true artichoke. See Jerusalem artichoke. George R. Hughes

Scientific classification. The artichoke belongs to the composite family, Compositae. Its scientific name is *Cynara scolymus.*

Article, in grammar, is the name given to one of three words—*a, an,* and *the.* They are classified as determiners and sometimes considered a separate part of speech. Determiners are used before nouns. They place limits on the noun rather than adding description.

The definite article is the word *the.* Speakers and writers use *the* before a noun when they believe their audience knows the identity of the noun that follows. The identity of the noun may be known because it refers to a unique person, place, object, action, quality, or idea. For example, in the sentence "She visited the Statue of Liberty," *the Statue of Liberty* refers to a unique object. The identity of the noun may also have been stated or may somehow have been made clear. From the sentence "Nancy bought two TV sets and a radio but had to return the TV's," *the TV's* clearly refers to the two that Nancy bought. "Hand me the hammer" makes sense only if the listener knows which hammer. The definite article can also be used with proper names to distinguish one person from others that may have the same name: "Is that *the* Michael Jordan?"

The indefinite articles are *a* and *an.* They are only used before singular nouns. Writers and speakers use the indefinite article when they believe their audience does not know the identity of the following noun. In the sentence "Mary handed the book to a boy," the writer does not believe that the reader knows which boy.

The article *an* is used before words beginning with a vowel sound, as in *an elephant.* It is also correct to say *an heir,* because the *h* at the beginning of *heir* is silent. However, *a* is used in the expression *a one-sided argument* because *one* begins with a *w* sound.

General use of articles. Sometimes articles refer to an entire class of objects instead of particular ones. For example, it is possible to talk of elephants in general in each of the following ways: "*The* elephant has long tusks." "*An* elephant has long tusks." "Elephants have long tusks." However, when the idea of the sentence only applies to an entire class, *a* and *an* cannot be used. For this reason, one cannot say "*An* elephant is in danger of extinction."

Usage of articles is often inconsistent. For example, we say *to school* but *to the library.* Such nouns as *flour* and *milk,* which are thought of collectively, do not require articles: "Milk is good for you."

Using or omitting the article often changes the meaning of a sentence. The following three sentences are examples: "A revolution changed the government." "The revolution changed the government." "Revolution changed the government." The first sentence mentions a revolution, but does not specify any particular one. The second sentence refers to a particular revolution previously mentioned or known to the reader. The third sentence refers to revolution as a process. Unnecessary articles often appear after such expressions as *kind of* or *sort of.* For example, *that kind of hat,* not *that kind of a hat,* is standard usage. Susan M. Gass

Articles of Confederation was the agreement under which the 13 original states established a federal government in 1781. The states called their confederation the United States of America, continuing the name used in the Declaration of Independence. The Articles of Confederation served as the new nation's basic charter of government until the first government under the Constitution of the United States was formed in 1789. The *Congress of the Confederation* operated the govern-

ment under the Articles of Confederation.

The Articles attempted to balance the need for an effective national government with the traditional independence of each state. The document guaranteed each state sovereignty and granted each state one vote in Congress. Under the Articles, Congress could not levy taxes, regulate trade, or force states to fulfill their obligations. However, the Articles did allow Congress to declare war and peace, manage foreign relations, establish and command an army and navy, and issue and borrow money.

The Second Continental Congress drafted the Articles of Confederation. Richard Henry Lee of Virginia first proposed the establishment of a confederation in the Congress on June 7, 1776. Congress appointed a committee to draw up a plan of union. Within a month, John Dickinson of Pennsylvania prepared a first draft. On Nov. 15, 1777, Congress adopted a final version. By 1779, all the states except Maryland had *ratified* (approved) it. Maryland withheld its approval until Virginia, New York, and other states had agreed to give Congress title to lands the states had claimed northwest of the Ohio River. The states promised to do so, and Maryland approved the Articles on March 1, 1781. The Articles went into effect on that date.

Even at the time the Articles of Confederation went into effect, many national leaders thought that the agreement did not give Congress enough power to operate effectively. But amendments were difficult to pass because all 13 states had to approve them. By 1786, James Madison, Alexander Hamilton, and others were convinced that a general convention was needed to make changes in the Articles. In September 1786, delegates from five states met at Annapolis, Maryland, and proposed that such a convention meet in Philadelphia in May 1787. Eventually, every state approved the proposal except Rhode Island.

The Constitutional Convention quickly agreed that the Articles had to be abandoned. The convention delegates wrote an entirely new document to replace the Articles—the Constitution of the United States. The Constitution greatly increased the power of Congress. It was ratified in June 1788. Jack N. Rakove

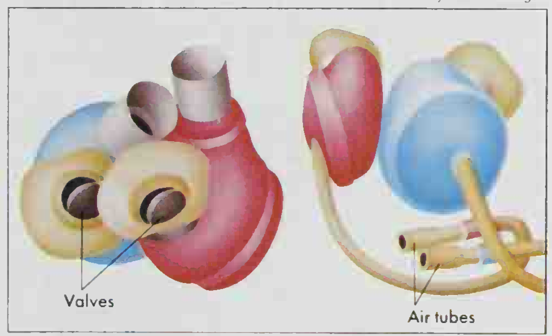
Articles of War governed the conduct of United States Army personnel until 1951, when the Uniform Code of Military Justice became effective. The Continental Congress adopted the articles in 1775 to administer justice and enforce discipline in the Continental Army. The Articles of War were based on a British Army Code adopted in the English Mutiny Act of 1689. They were revised in 1776, 1786, 1806, and again in 1916. Congress made other changes after both World Wars I and II, chiefly to assure more leniency in the articles. In 1950, it established the Uniform Code of Military Justice and applied it to all branches of the U.S. armed services. The Uniform Code replaced the Articles of War.

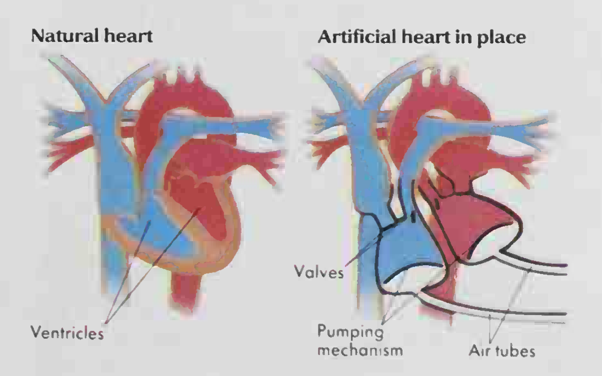
Joel D. Meyerson

See also Uniform Code of Military Justice.

Artificial eye is worn by a person who has had an eye removed because of disease or injury. When the eye is removed, a surgeon cuts free the optic nerve and the muscles that move the eye. The surgeon places a plastic, metal, or ceramic ball into the cavity and sews the muscles and conjunctival tissue together in front of the ball.



The artificial eye itself is a curved shell of lightweight plastic or glass that is painted to match the normal eye. It fits between the eyelids and the tissue covering the ball. Muscle movement causes the artificial eye to move. If movement is good, it is hard to notice an artificial eye. An artificial eye requires little care. David E. Eifrig



Artificial heart is a device designed to replace a natural heart. Like the natural heart, it has two *ventricles* (chambers) that pump blood through the body. One ventricle supplies blood to the lungs, and the other provides circulation for the rest of the body. Artificial hearts are currently used in extremely ill patients awaiting a donor heart for transplantation. Artificial hearts are designed to fit in the space that remains when a diseased natural heart is removed.

An air-powered artificial heart

Like a natural heart, an air-powered artificial heart has two *ventricles* (chambers). Each ventricle has inlet and outlet valves. A disk-shaped pumping mechanism in each ventricle expands and contracts to send blood through the body. Air tubes connect the ventricles with a power system that drives the pumps.

WORLD BOOK illustrations by Leonard Morgan

Artificial hearts consist of two pumps, each with separate inlet and outlet valves, and a system to regulate the pumping rate. Materials used to make artificial hearts include polyurethane and other plastics, and titanium.

The artificial heart was invented by scientists led by Willem Kolff, a Dutch-born physician. He first tested the device in an animal in 1957. The first use of an artificial heart in a human being occurred in 1969. That year, a team of surgeons headed by Denton A. Cooley of the Texas Heart Institute used the device to temporarily support blood circulation in a patient until a natural heart became available for transplantation.

Scientists have worked to develop an artificial heart that can permanently replace a diseased human heart. In 1982, a surgical team led by William C. DeVries of the University of Utah implanted an air-powered device as the first permanent artificial heart. The device used, an air-powered Jarvik-7 heart, was designed by the American physician Robert K. Jarvik. The recipient, Barney B. Clark, survived for 112 days. Several other patients also received Jarvik hearts as permanent replacements, and one survived for 620 days.

Scientists abandoned air-powered permanent artificial hearts, however, in the late 1980's. Some patients had suffered strokes caused by blood clots that formed in the pumps and then broke off and blocked brain arteries. Scientists also had become concerned for the patients' quality of life. The device had a large external power unit that hampered movement and air tubes that passed through the skin.

In the 1990's, scientists concentrated on developing an artificial heart run by a compact electric motor inside the body and a battery pack outside. A process called *inductive coupling* transmits power from the batteries to the motor without piercing the skin. This new type of artificial heart was introduced in 2001. The recipient died 151 days later from complications unrelated to the function of the heart. Other patients have since received the device. William S. Pierce

Artificial intelligence (AI) is a branch of computer science that strives to design systems that process information in a manner similar to the way a person thinks. A computer with artificial intelligence could perform such tasks as understanding language, planning to accomplish goals, learning from experience, and perceiving the world through vision, hearing, and other senses.

AI as a scientific field began at a workshop at Dartmouth College in 1956. John McCarthy, a Dartmouth professor, organized the workshop and coined the name of the new discipline. At the meeting, scientists presented the first computer programs capable of logical reasoning, learning, and playing board games.

AI is typically divided into six main categories: (1) knowledge representation and reasoning, (2) planning and problem solving, (3) natural language processing, (4) machine learning, (5) computer vision, and (6) robotics.

Knowledge representation and reasoning are two core problems in AI. There are three main approaches to these problems: (1) the logical approach, (2) the probabilistic approach, and (3) the neural network approach.

In the logical approach, programs reach conclusions based on series of "if-then" rules. A simple series of such rules might be structured as "If x is true and y is true, then z is true." The logical approach has led to the development of *expert systems* that solve particular problems. Such systems have been used in such fields as chemistry, geology, and medicine. However, each program requires many detailed rules and cannot reason effectively outside a narrow range of expertise.

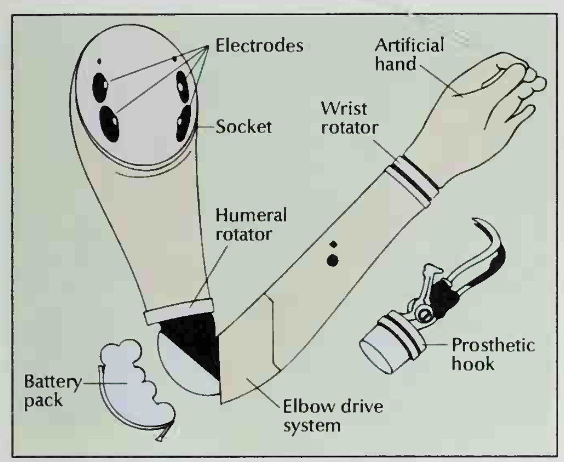
In the probabilistic approach, knowledge is represented as numerical probabilities. Reasoning involves computing the probability of alternative conclusions given specific evidence.

In the neural network approach, knowledge is represented as a network of interconnected units that can perform certain tasks by exchanging information. This approach mimics the behavior of *neurons*, the cells in the brain that process information.

Planning and problem solving programs may seek sequences of actions that accomplish specified goals. Such programs search a large number of alternative plans guided by *heuristics*, rules that direct the search toward promising solutions. A common type of problem solving involves playing board games. Computers have been programmed so that they can play many board games at the level of the best human players.

Natural language processing involves computer programs that communicate in a human language, such as English, instead of a specialized programming language. Scientists have developed logical, probabilistic, and neural network systems for understanding natural language. Modern systems can successfully carry on conversations about a narrow topic, such as making airline reservations. But they can understand and produce only a limited range of sentences.

Machine learning involves computer programs that learn from examples and from experience. The 1956 Dartmouth workshop presented the first program that learned to play checkers by competing against a copy of itself. Other programs have learned to play backgammon and to recognize human speech and handwriting.



Computer vision attempts to build computers that can recognize patterns and objects in visual images. Vision systems first extract image features, such as edges and textures, then use rules or neural networks to identify objects in the scene. For example, systems can identify military equipment in aerial images.

Robotics studies the control of mechanical robots. Robots must control their motion to manipulate objects and avoid obstacles. Robotics enables machines to perform complicated tasks by combining motion planning, interpretation of visual and sound information, and artificial speech. Raymond J. Mooney

See also Robot; Turing, Alan M.

Artificial limb is a synthetic replacement for an arm or leg lost as the result of injury, disease, or a birth defect. An artificial limb is also called a *prosthesis*. No artificial limb can perform all the functions of a human limb, but a well-fitted prosthesis can help a person participate in most everyday activities.

Preparation of an artificial limb. A prosthesis must be custom made for each patient. In most cases involving an amputated limb, the remaining stump must heal and shrink before it can be fitted with a permanent prosthesis. For several weeks, the stump may be wrapped tightly with elastic bandages to help it shrink to a firm, smooth surface. In some cases, the person wears a rigid plaster cast, to which a temporary prosthesis can be at-

WORLD BOOK diagram by Bill Anderson

A myoelectric artificial arm responds to muscle contractions in the remaining upper arm or shoulder. The contractions generate a tiny electric current, which is picked up by electrodes in the socket of the artificial arm. The current controls the output of the battery pack, which powers a motor that bends the elbow. The arm can be fitted with an artificial hand or a prosthetic hook.

tached. During this time, the person exercises the remaining limb muscles to preserve their strength and movement, and to promote circulation.

The next step in preparing a prosthesis involves making a plastic socket that will fit over the stump snugly and comfortably. A cast for the socket may be obtained by wrapping the stump with bandages soaked in wet plaster and letting them harden. After the bandages are removed, they form a mold. Liquid plaster poured into this mold provides a model of the stump. A plastic socket is then formed over the model.

An artificial arm or leg is attached to the socket. Materials used in making artificial limbs include plastic, fiberglass, metal, and wood. Light metal supports attached to the socket may contain an artificial joint to replace an elbow or a knee. The prosthesis ends in a substitute hand or foot. Hand substitutes look like a real hand. A foot substitute has the same general shape as a normal foot. Most prostheses stay on the body with straps or suction.

Control of artificial limbs. Most artificial arms are controlled by a cable that loops around the opposite shoulder. Movements of that shoulder produce movement in the arm prosthesis. Artificial legs are chiefly controlled by the body's normal walking movements.

In the early 1960's, researchers developed a type of prosthesis that was controlled by *myoelectricity*—the electric current produced when a muscle contracts. Metal disks inside the socket rest against the skin of the stump. The disks pick up myoelectric impulses, which are then amplified and used to control an electric motor in the prosthesis. In most myoelectric arms, impulses from one muscle bend the arm, and those from another muscle straighten it. Similarly, impulses from one arm muscle open a myoelectric hand, and those from another muscle close it. These actions are somewhat like an arm's natural muscle contractions. Dudley S. Childress

Artificial sweetener is a synthetic substance used in food and beverages in place of sugar. Artificial sweeteners are sweeter and have fewer calories than *sucrose* (table sugar). They are widely used by people dieting to lose weight and by people with diabetes.

In the United States, the Food and Drug Administration (FDA) regulates the use of artificial sweeteners. The FDA has prohibited the use of several of the substances because experiments indicated they could cause cancer in people. For example, artificial sweeteners called cyclamates were banned in the United States in 1970. However, they are still used in other countries. The artificial sweeteners approved for use in the United States are aspartame, saccharin, acesulfame-K, and sucralose.

Aspartame is the most widely used artificial sweetener. It is derived from aspartic acid and phenylalanine, chemicals that occur in some foods. It is about 200 times as sweet as sucrose. Aspartame was first produced in 1965. Early experiments suggested that eating large amounts of it might cause brain damage. But in 1981, the FDA concluded that aspartame posed no significant health risk. The FDA has approved it for use in breakfast cereals, soft drinks, chewing gum, and other products.

Saccharin is about 300 times as sweet as sucrose. It is made from toluene and from petroleum. Testing done in the mid-1970's indicated that large doses of saccharin produced cancer in rats and that it may do so in people as well. Several countries have banned the use of saccharin. In 1977, the FDA took steps to ban saccharin use in the United States. But Congress postponed the ban. In 1981, the National Toxicology Program (NTP), a part of the U.S. Department of Health and Human Services, added saccharin to its list of known human *carcinogens* (substances that can cause cancer). But in 2000, the NTP removed it from the list. The NTP said that the link to cancer does not apply to human beings. See Saccharin.

Acesulfame-K, also called acesulfame-potassium, is derived from acetoacetic acid. It is about 200 times as sweet as sucrose. The FDA approved the use of acesulfame-K in dry goods in 1988. The sweetener is now used in many other products, including yogurt, baked goods, and soft drinks, and as a sugar substitute.

Sucralose is about 600 times as sweet as sucrose. It is made from modified sugar molecules. The body does not recognize it as a sugar and so does not absorb it. Thus, sucralose supplies no calories. The FDA approved the sweetener in 1998 for use in the same foods for which aspartame has been approved. Canada has also approved the use of sucralose. Johanna T. Dwyer

See also Food additive.

Artificial turf is a manufactured product that looks like grass. Athletic stadiums and recreation departments use it as a playing surface for indoor and outdoor activities. Artificial turf is also used in landscaping, patios, highway medians, and doormats. Manufacturers have developed many varieties of artificial turf since it first came into use in the early 1960's.

The surface of artificial turf consists of tough nylon fibers or similar material woven into a base pad of the same material like a household carpet. The base pad is glued to a rubber pad about 1 inch (2.5 centimeters) thick. The rubber pad is glued to a foundation consisting of a layer of asphalt about 5 inches (12.5 centimeters) thick that covers a layer of gravel or other porous material about 18 inches (46 centimeters) thick. Modern foundations have special drainage systems that prevent water from accumulating on the playing surface.

Unlike grass, artificial turf does not require costly care and is not damaged by hard use in sports. Its surface stays smooth and even, and weather does not affect it. Artificial turf also has some disadvantages. Some athletes and doctors believe that the additional traction and the hard subsurface cause knee injuries. The turf also becomes hot in warm weather because the asphalt absorbs heat. John L. O'Donnell

Artigas, *ahr TEE gahs,* **José Gervasio,** *hoh SAY hehr VAH syoh* (1764-1850), was a leader in Uruguay's struggle for independence. In the early 1800's, he raised an army to free Uruguay from Spain. In 1814, however, troops from Argentina captured Montevideo, Uruguay's chief city. In 1815, Artigas gained control of Montevideo for Uruguay. For a short time that year, he governed most of Uruguay and parts of Argentina. But Portuguese troops from Brazil captured Montevideo in 1817, and Artigas fled to Paraguay in 1820. Uruguay did not gain its independence until 1828. Artigas was born in Montevideo. See Uruguay (Independence). Michael L. Conniff

Artillery, *ahr TIHL uhr ee,* includes mounted guns or rocket launchers that are too large or too heavy to be classed as small arms. In the United States, any gun or launcher that uses ammunition 1 inch (2.5 centimeters) or more in diameter, and that is not fired from the hand or shoulder, is called *artillery.*

Parts of a gun

An artillery piece consists of a *barrel* (tube) with two openings. The opening where the shell comes out is the *muzzle.* The *breech* is the opening where the ammunition is inserted. The weapon's size is given in terms of its *caliber* (diameter of the bore or ammunition). The *breechblock* closes the breech and usually contains the firing pin or firing mechanism.

U.S. Army

Antiaircraft artillery protects troops and military installations from air attack. A Vulcan 20-millimeter cannon, *shown here,* has six rotating barrels and can fire over a ton of shells per minute.

U.S. Army

Field artillery like this howitzer support infantry and armored forces. Light and medium artillery, which range from 75 to 155 millimeters, can be transported by truck or helicopter.

Guns may have either a rifled or a smooth bore. *Rifled* bores have spiraled grooves that spin and steady the shell, so it will travel nose-first to the target. *Smoothbore* guns use ammunition with fins that steady shells in flight. The firing mechanism contains a *primer* for large caliber guns, or a firing pin for smaller weapons. The primer ignites the propellant in the ammunition. The propellant develops a very high pressure that forces the projectile out of the muzzle at high *velocity* (speed).

Kinds of artillery

Artillery is classified according to size as light artillery, medium artillery, and heavy artillery. It may also be classified by the *trajectory* (curved path of flight) it imparts to the projectile. *Guns* use a low, flat trajectory at high muzzle velocity. *Howitzers* use a high arc trajectory against targets hidden behind obstacles. Mortars, rocket launchers, and recoilless rifles are often considered artillery. *Mortars* usually have a smooth bore and are loaded from the muzzle. They send projectiles in higher arc trajectories than howitzers. *Rocket launchers* start the rockets on their flights. *Recoilless rifles* fire shells the size of small caliber artillery shells. They are much lighter than other artillery weapons. These rifles may be carried by hand or mounted on vehicles.

Field artillery is used to support infantry and armored forces. The weapons may be towed by tractors or trucks or mounted on vehicles so they can be brought into action quickly. They vary in size from guns firing 1-pound (0.5-kilogram) projectiles to those firing 350-pound (159-kilogram) projectiles. Ammunition trailers and tractors have replaced the *caissons* (ammunition wagons) that were once used to carry ammunition for field artillery. Weapons ranging from 75 to 125 millimeters are mounted on tanks and tank destroyers. Surface-to-surface guided missiles supplement field artillery.

Antiaircraft artillery can fire shells rapidly at high angles. The guns are usually aimed at the target by electronic automatic fire control systems. Generally, special fuses are used to explode the shells in the area of the

U.S. Army

A self-propelled howitzer, *shown here,* can be driven without being towed. This 155-millimeter howitzer can fire 95-pound (43-kilogram) shells about 9 miles (14 kilometers).

target. Antiaircraft guns are often supported by surface-to-air missiles.

Other artillery. Cannon mounted in airplanes and helicopters and on naval vessels are sometimes called artillery. See **Air force; Cannon; Warship.**

How artillery is made

Until after the American Civil War (1861-1865), almost all cannon were cast in brass, bronze, or cast iron. To make the cannon stronger, manufacturers added more metal to make the barrel walls thicker.

Later in the 1800's, manufacturers made larger guns by *forging.* In forging, workers melt the steel in a furnace, then pour it into a gun or ingot mold to cool. They reheat the metal to about 2100 °F (1150 °C) and use hydraulic hammers or presses to forge it into shape.

The mono-block process. Most gun tubes today are made by the *mono-block* method because of the development of high-strength steels. By this process, manufacturers make the tube stronger by expanding it under internal pressure until the interior diameter of the tube has been permanently enlarged. The outer layers of metal tend to shrink to their original dimensions when the pressure is released, but the inner layers tend to keep their enlarged diameter. This compresses the inner layers. This process is also called *cold working* or *autofrettage.* After the tube has been formed, it is *annealed* (tempered) by being heated and slowly cooled. Workers then machine it to its final specifications.

U.S. Army

Hawk missiles, *shown here,* can attack aircraft flying as low as 100 feet (30 meters). The Hawk uses a radar echo from its target to locate the target. These missiles are 12 feet (3.7 meters) long.

Rifling. After final machining, the gun is *rifled.* In this process, workers cut grooves in the finished bore surface of the gun. Instead of cutting these grooves directly into the barrel, workers sometimes cut them into a separate tube called a *liner,* which can be inserted into the barrel. One advantage of a rifled liner is that it can be replaced with a new liner when it becomes worn. But higher construction costs have limited their use.

History

Artillery was first used during the 1300's. The French used small cannon against the English in 1450, and the Ottomans under Mehmet II used artillery in the final campaign to capture Constantinople in 1453. From these early beginnings, guns have increased enormously in size, firepower, and accuracy. Artillery played an ever-increasing part in battles. Napoleon was the first general to collect his artillery in a *grande batterie* (big battery). He concentrated his artillery fire on one point in the enemy's line, and then sent troops against that point.

During World War I (1914-1918), troops on the Western Front dug great mazes of trenches and fought from fairly fixed positions. Much of the fighting consisted of exchanges of fire between big-gun batteries. In 1918, the Germans shelled Paris with guns known at the time as "Big Berthas." These huge guns hurled shells 15 $\frac{1}{2}$ miles (24.9 kilometers) above the surface of the earth toward a target up to 75 miles (120 kilometers) away.

Giant guns had little place in World War II (1939-1945). They could not move fast enough to keep up with the rapid changes in battle lines. Airplanes could easily destroy fixed batteries of large guns. The greatest artillery advances during the war were in the power and mobility of smaller weapons. Helicopters now carry artillery into battle in a procedure known as *airmobility.*

On May 29, 1953, the United States fired the first atomic artillery shell from a 280-millimeter cannon. Today, artillery weapons of smaller calibers can fire atomic projectiles. Joel D. Meyerson

Arts and Sciences, American Academy of, is one of the oldest learned societies in the United States. It was founded in 1780 to advance research and to promote the study of national and international problems. It has about 3,300 members. Members are chosen for achievements in scholarship, the arts, the professions, or public affairs.

The academy administers funds for research and awards prizes for outstanding achievement, including the Rumford Medal in the physical and biological sciences and the Emerson-Thoreau Medal in literature. One of the academy's main activities is to appraise current and emerging issues in such areas as arms control, education, and economic development. The academy publishes the journal *Daedalus.* Headquarters of the academy are in Cambridge, Massachusetts.

Aruba, *ah ROO bah,* is an island in the West Indies that belongs to the Netherlands. For location, see **West Indies** (map). Aruba covers 75 square miles (193 square kilometers) and has a population of about 112,000. Oranjestad is the capital and largest city.

Aruba is a hilly, rocky island that supports little agriculture. But it has coral reefs, white sand beaches, and a warm, dry climate that attract many tourists. Aruba's population includes American Indians, blacks, whites, and people of mixed ancestry. Most of the people work in government jobs, in the tourist business, or in a refining industry that processes crude oil imported from nearby Venezuela.

American Indians were the first inhabitants of Aruba. The Netherlands gained control of the island in 1634. It made Aruba part of its island colony called the Netherlands Antilles (see **Netherlands Antilles**). In the mid-1970's, some Arubans began seeking independence from both the Netherlands and the other islands of the Netherlands Antilles. An agreement between Aruba and the Netherlands resulted in Aruba's separation from the Netherlands Antilles in 1986. Aruba has self-government, but the Netherlands is responsible for its defense and foreign affairs. Gary Brana-Shute

Arum, *AIR uhm,* is the name of a large family of plants. There are over 2,000 species of arums. Most grow in tropical and subtropical regions, but some are found in temperate areas. Many arums are poisonous.

WORLD BOOK illustration by Christabel King

The cuckoopint is a type of arum that grows in Europe. It bears tiny flowers surrounded by a leaflike *spathe.*

The arum plant bears a flower cluster made up of tiny blossoms. The blossoms grow at the tip of a slender stalk called the *spadix* and are surrounded by a colorful, leaflike *spathe.* Arums that grow wild in North America include the water arum, jack-in-the-pulpit, skunk cabbage, and sweet flag. True arums are native to the Eastern Hemisphere and make up a small group in the arum family. The *cuckoopint,* also known as *lords-and-ladies,* is a true arum that grows in Europe. It resembles the jack-in-the-pulpit. Kenneth R. Robertson

Scientific classification. Arums make up the arum family, Araceae. The cuckoopint is *Arum maculatum.*

Aryans, *AIR ee uhnz,* is a term used both for a group of Asian languages and for certain Asian peoples. *Indo-Aryan* is a group of languages spoken mainly on the Indian subcontinent. Some of these languages date back to as long ago as about 1500 B.C. Indo-Aryan includes the ancient Sanskrit language and the modern Hindi. In Sanskrit, the term *arya* referred to a group of people in ancient India. These Aryans were Brahmans, members

Aruba Tourist Bureau

Aruba is a scenic island in the West Indies. Tourists enjoy its beautiful, white sand beaches and warm, dry climate.

of the highest Hindu caste, who followed the traditionally accepted religious practices and used Sanskrit. In Sanskrit, *arya* means *kinsmen* or *nobles.*

Other peoples that referred to themselves as Aryans were the Iranians, including the Persian family of rulers known as the *Achaemenids.* The Indo-Iranians settled about 1500 B.C. in what are now Afghanistan, northern India, Iran, and Pakistan. The Achaemenid family ruled what is now Iran from about 550 B.C. to 331 B.C. The name *Iran* comes from the word *Aryan.*

In the mid-1900's, the rulers of Nazi Germany used the term *Aryan* to refer to Germans and certain other northern Europeans, whom they considered racially superior to all other peoples. This racist use of the term has continued among certain white supremacist groups in the United States. George Cardona

Asbestos, *as BEHS tuhs,* is any of a group of soft, threadlike mineral fibers. Asbestos has many properties that make it commercially valuable. It does not burn or easily conduct heat or electricity. It is also flexible and strong and is not affected by most chemicals. Asbestos occurs in certain types of rocks, which are mined and then processed to remove the asbestos fibers.

Asbestos can cause health problems if it is inhaled. It is thought to present no health hazard so long as it remains intact. It is believed to become dangerous only after it crumbles and releases its tiny fibers into the air. Asbestos that is dry and capable of crumbling with the slightest pressure is said to be *friable.* Such asbestos is associated with a disease called *asbestosis.* It is also associated with certain types of cancer.

Asbestos use has declined since the 1970's due to the health problems associated with the mineral. Today, manufacturers make only a few types of products that contain asbestos. These include automobile parts and building materials.

Types of asbestos. Geologists use the word *asbestos* to refer to the fibrous varieties of certain *hydrated silicates.* Hydrated silicates are minerals that are composed of silica and a metallic element, which are chemically combined with water. The fibrous hydrated silicates that make up asbestos belong to either the *serpentine group* of minerals or to the *amphibole group* of minerals.

WORLD BOOK photo, courtesy Field Museum

Asbestos is a soft, threadlike mineral fiber in certain types of rock, as shown here. The rock is mined and hauled to a plant where a series of machines crush it to free the asbestos fibers.

The serpentine mineral group includes *chrysotile,* the best known, most abundant, and most widely used type of asbestos. Its chemical formula is $Mg_3Si_2(OH)_4O_5$. The crystal structure of chrysotile consists of alternate sheets of magnesia and silica. These sheets are coiled into tubes called *fibrils* that resemble a rolled newspaper.

The amphibole mineral group consists of several types of asbestos. The most abundant types are *crocidolite* and *amosite.* Amphibole asbestos has coarser fibers than does chrysotile. These types of asbestos also consist of hydrated silicates plus other elements. The crystal structure of amphibole asbestos is made up of a chain of silicon and oxygen atoms. Atoms of other elements are coordinated with this chain. The strands of amphibole fibers are parallel to the chain of atoms.

Uses of asbestos. Each type of asbestos has certain qualities, and so each kind is used for different purposes. For example, most chrysotile has fine, curly fibers that are strong and resist heat. Manufacturers use chrysotile for such products as roof coatings and roof cements, asbestos cement sheets, and siding and shingles for houses. Chrysotile is also used for asbestos cement water pipes and for packings and gaskets used in the automotive and petrochemical industries. Short chrysotile fibers are used to make materials that can withstand heat generated by friction, such as brake linings for motor vehicles.

Amphibole asbestos is noted for its high resistance to heat and acids. Crocidolite is used in asbestos cement pipes and in diaphragms involved in the production of chlorine.

Sources of asbestos. Most asbestos is found in *metamorphic rocks* (see Metamorphic rock). Chrysotile develops mainly as deposits in the cracks and seams of such rocks. Amosite and crocidolite, the most abundant types of amphibole asbestos, occur chiefly in highly folded metamorphic rocks.

Each year, about 2 $\frac{1}{2}$ million tons (2.3 million metric tons) of asbestos are produced throughout the world. Russia produces about one-third of the world's asbestos, and Canada produces about one-fourth. Brazil, China, Kazakhstan, and Zimbabwe are other leading producers.

How asbestos is mined and processed. Most asbestos is obtained from enormous pits dug in the ground. This process is called *open-pit mining.* But some asbestos deposits are mined underground.

After the rocks have been mined, trucks take them to a plant called a *mill.* There, a series of machines crush the rocks into progressively smaller pieces with little damage to the fibers. In one common method, the loose fibers are *aspirated* (drawn by suction) through screens that allow only the asbestos to pass through. Special equipment divides the fibers according to length. The asbestos is then shipped to manufacturers.

Hazards of asbestos. People who mine asbestos, manufacture asbestos products, install asbestos insulation, or remove asbestos may inhale the fibers. People who hold such jobs in countries that do not limit work-

ers' exposure to asbestos are at high risk of contracting a disease related to asbestos. Also at high risk are workers who held such jobs for many years before exposure was limited by law. In addition, asbestos can be a hazard to the families of asbestos workers, who may carry asbestos dust home on their clothing. Asbestos dust may also affect people who live near asbestos mines or processing plants.

Asbestosis is a disease that blocks the lungs with scarred tissue. This condition causes shortness of breath. Another disease associated with asbestos is lung cancer. Asbestos workers who smoke are at an even higher risk for lung cancer. Asbestos also causes *mesothelioma,* a rare and fatal cancer of the lining of the chest or abdomen.

Scientists do not know exactly how asbestos causes disease. Many researchers say that inhaling fibers longer than 5 to 10 micrometers (0.0002 to 0.0004 inch) and less than 2 micrometers (0.00008 inch) wide increases the risk of illness. Inhaling fibers for even a short amount of time may result in mesothelioma.

In the United States, government regulations established by the Occupational Safety and Health Administration (OSHA) limit the hazard of asbestos among workers. Government regulations also protect consumers from certain products containing asbestos.

History. The properties of asbestos have been known since ancient times. The Egyptians used asbestos cloth to prepare bodies for burial. The Romans collected the ashes of the dead by wrapping the bodies in asbestos cloth before cremation.

In 1774, Abraham G. Werner, a German mineralogist, wrote the first comprehensive scientific description of asbestos. People did not become aware of the health hazards of asbestos until the early 1900's. The United Kingdom, in 1931, was probably the first country to establish health laws regulating exposure to asbestos. In 1935, the Canadian province of British Columbia passed a law requiring asbestos workers to wear protective equipment when working with asbestos. The United States enacted similar standards into law in 1972.

In 1973, the U.S. Environmental Protection Agency (EPA) banned the use of sprayed asbestos for insulation or fireproofing. In 1975, this ban was expanded to include wet applications of asbestos, such as application with a trowel, and the use of molded asbestos that could become friable.

In 1986, the EPA began a program to reduce the danger of asbestos in all public and private primary and secondary school buildings. These structures must be inspected to determine the amount of asbestos in them, and its location and condition. If a building contains asbestos, the school must develop and implement an asbestos management plan. The EPA also ordered that any removal, encapsulation, or enclosure of asbestos be followed by tests to ensure that the amount of asbestos has been reduced to a safe level. Synthetic fibers of fiberglass and plastics are being used as a substitute for asbestos fibers. James R. Kramer

Asbjørnsen, *AHS byurn suhn,* **Peter Christen,** *PAY tuhr KRIHS tuhn* (1812-1885), was a collector of Norwegian folk tales and a naturalist. He won fame for his work with Jørgen Moe in immortalizing the tales told by the people of Norway. Their collection, *Norwegian Folk Tales* (1842-1843), became a classic of Norwegian and world literature. It includes such diverse stories as "The Three Billy Goats Gruff," "Mastermaid," and "Little Per and Big Per."

Asbjornsen was born on Jan. 15, 1812, in Christiania (now Oslo). He explored the coasts of Norway, and made important contributions to botany and zoology.

Niels Ingwersen

Asbury, *AZ buh ree,* **Francis** (1745-1816), was the most important Methodist leader in America during the late 1700's and early 1800's. Asbury was born in England, but he lived in America from 1771 until his death. When Asbury arrived in America, there were only a few hundred Methodists in scattered, disorganized groups. Under his leadership, the Methodists increased in number until they ranked second only to the Baptists as the largest Protestant denomination in America.

Asbury was born on Aug. 20, 1745, near Birmingham, England. He became a Methodist while a teen-ager. He was a traveling preacher from 1767 to 1771, when he volunteered to go to America as a missionary. The other Methodist missionaries returned to Britain after the colonists rebelled against Britain. But Asbury stayed in America.

In 1784, Asbury became a superintendent, or bishop, of the newly founded Methodist Episcopal Church. He gained this position by order of the Methodist leader John Wesley and by a vote of the Methodist preachers in America. The church lacked enough formally educated ministers to serve the growing American population, and so Asbury expanded the Methodist technique of enlisting laymen to lead local congregations. From these laymen, he recruited many young preachers to travel on horseback among frontier congregations, overseeing local meetings and conducting public worship. These preachers were called *circuit riders.* They were supervised by more experienced preachers called *presiding elders.* Asbury supervised the system.

Asbury traveled almost constantly, riding from 4,000 to 6,000 miles (6,400 to 9,700 kilometers) a year on horseback. He planned a large number of religious gatherings, especially camp meetings where thousands of people gathered outdoors in order to sing hymns and hear sermons. Mark A. Noll

Ascension, *uh SEHN shuhn,* is an island in the South Atlantic about 700 miles (1,100 kilometers) northwest of Saint Helena and 500 miles (800 kilometers) south of the equator. It belongs to the United Kingdom and is under the administration of Saint Helena (see **Saint Helena**). It has an area of 34 square miles (88 square kilometers), and a population of about 1,000. The island is a breeding ground for sea turtles and the sooty tern. For location, see **Atlantic Ocean** (map). Hartmut S. Walter

Asceticism, *uh SEHT uh sihz uhm,* is the practice of self-denial or self-punishment, often for religious purposes. Those who practice asceticism are called *ascetics.* They may go for long periods without food or sleep, wear rough clothing, expose themselves to extreme heat or cold, or refrain from sexual relations. Some even whip themselves or stick sharp objects in their skin.

Ascetics believe a person's physical life conflicts with

his or her spiritual life. Ascetics strive to become more spiritual by denying themselves physical pleasures and many necessities. Sometimes, ascetic practices produce religious visions, which ascetics regard as a sign of their increasing spirituality.

Asceticism has been a part of religious traditions for thousands of years. Many early Christians gave up physical comforts to become closer to God. Asceticism has been especially important in Roman Catholicism and certain religions of India and Japan. Nancy E. Auer Falk

Asch, *ash,* **Sholem,** *SHAW luhm* (1880-1957), a Polish-born author, was the first person to achieve international recognition writing in Yiddish. Asch's heroes search for faith and yearn for an ideal. A major theme of his works is that the individual, no matter how sinful, strives for holiness.

Asch first gained fame for his novel *A Shtetl* (*A Town,* 1904). This work introduced a new romantic tone into Yiddish literature. Earlier Yiddish writers had portrayed Jewish life in eastern Europe in a largely negative way. In *A Shtetl,* Asch stressed its harmony, strength, and respect for tradition.

Asch was fascinated with the relation between Christianity and Judaism. He wrote three related biographical novels about the founders of Christianity—*The Nazarene* (1939), *The Apostle* (1943), and *Mary* (1949). He hoped that his presentation of Christianity's Jewish heritage would reduce prejudice against Jews. However, many Jewish critics attacked Asch for what they believed was a move away from Judaism toward Christianity. Asch also became known for his plays, most notably *God of Vengeance* (1907). Asch was born in Kutno, Poland, on Nov. 1, 1880. He moved to the United States in 1914 and became a U.S. citizen in 1920. Eugene V. Orenstein

Ascidian. See Sea squirt.

Asclepius, *uh SKLEE pee uhs,* was the god of healing in Greek mythology. The Romans called him Aesculapius. The Greeks prayed to Asclepius during plagues and in times of illness. His best-known child was Hygeia, the goddess of health. Epidaurus in Greece was the special site of his followers, the Asclepiads, the first physicians. Asclepius's symbol, a snake entwined around a staff, is often used as a symbol of the medical profession.

Asclepius's father was the god Apollo, who taught his son the art of health. But Asclepius misused this gift by trying to revive a dead man. Zeus, ruler of the gods, therefore killed him with a thunderbolt and sent him to Hades, god of the underworld. Nancy Felson

Ash is a group of hardwood trees found in North America, Europe, and Asia. There are 16 species in the United States. Some are commercially valuable. Ashes may be planted as shade trees to prevent soil erosion. *White ash* and *red ash* are common in the eastern United States. *Black ash* is found in the northeastern United States.

Ash leaves and branches develop in pairs. Each leaf has from 5 to 11 pointed leaflets. Small male and female flowers usually grow on separate trees. The *keys* (winged fruit) look like canoe paddles. They develop late in the season and fall to the ground in autumn.

Ash wood is hard, strong, and stiff. The wood is used mainly for shovel, hoe, and rake handles and for baseball bats. Ash is also used for furniture, oars, and skis.

Norman L. Christensen, Jr.

Scientific classification. Ashes belong to the olive family, Oleaceae. White ash is *Fraxinus americana.* Red ash is *F. pennsylvanica.* Black ash is *F. nigra.*

See also Boxelder bug; Mountain ash; Prickly-ash; Tree (Familiar broadleaf and needleleaf trees [picture]).

Ash is the substance that remains after an organic substance has been burned. The word *ashes* usually refers to the minerals obtained from burning coal, wood, or other fuels. An analysis of the ashes of burned foods and other substances can determine the minerals they contain. For example, chemical tests of the ashes of burnt milk show that they contain calcium. Seaweed ash has a high iodine content. Some kinds of ashes can be used for various purposes. For example, *fly ash,* the dust produced by power plants that burn coal, is used as a soil fertilizer. Clark L. Fields

Ash Wednesday is the first day of Lent. The day marks the start of the season of discipline and penitence that continues through the Lenten season. The day is observed by Western Christian churches, especially Roman Catholic, Anglican, and Lutheran churches.

In many churches, the observance of Ash Wednesday centers on ashes from burned palms used in the previous year's Palm Sunday procession. A priest or pastor blesses the ashes and uses them to mark the foreheads of worshipers. This blessing is based on the Biblical passage, "for dust thou art, and unto dust shalt thou return." (Genesis 3:19). Ashes also serve as a symbol of purification and penitence. David G. Truemper

Ashanti, *uh SHAN tee* or *uh SHAHN tee,* are the largest and most powerful ethnic group in the West African country of Ghana. The group's name is also spelled *Asante.* Most of the approximately 1 $\frac{1}{2}$ million Ashanti live in south-central Ghana in the Ashanti Region. The capital of the region, Kumasi, is the second largest city in Ghana.

Most Ashanti make their living as farmers, raising cocoa and other crops. Others work in the mining or forestry industries or in business. Ashanti weavers are famous for producing colorful *kente cloth,* which has complicated patterns full of tiny details.

The Ashanti language is called Twi, but many Ashanti also speak English. A number of Ashanti are Christians, and some are Muslims. The traditional Ashanti religion involves a supreme god called Nyame, who communicates with human beings through lesser gods. The Ashanti also honor their ancestors at ancestral shrines.

The Ashanti probably descended from peoples who lived in western Africa thousands of years ago. During the late 1600's, a leader named Osei Tutu united the Ashanti into a single state and became the first *Asantehene* (king) of the unified nation. He made Kumasi the capital of his kingdom. The Ashanti developed a powerful army, which conquered many surrounding states during the 1700's. At its height in the early 1800's, the Ashanti Empire included much of modern-day Ghana,

eastern Côte d'Ivoire, and western Togo.

During the late 1800's, the Ashanti and the British fought each other for control of trade in West Africa. In 1901, the British defeated the Ashanti and made the Ashanti lands a British colony. The colony, called Ashanti, was subject to the authority of another British colony, the Gold Coast. In 1957, Ashanti, the Gold Coast, and other nearby areas controlled by the United Kingdom became the independent country of Ghana. Since then, the Ashanti have played a major role in Ghana's economic and political development. Dennis M. Warren

Ashbery, John (1927-), is an American poet. His poems have no realistic or logical beginning, middle, and end, imitating instead the fluidity of thought. Their dreamlike structures often consist of melodious fragments of colloquial speech. Critics have been puzzled by Ashbery's unconventional, obscure works, but they have praised his technique and use of language.

Ashbery served as a magazine and newspaper art critic for many years, and art themes appear in his verse. He won the 1976 Pulitzer Prize for poetry for *Self-Portrait in a Convex Mirror.* The title poem in this collection is a dreamy reflection on time and space in art inspired by a painting by the Renaissance artist Parmigianino.

Ashbery was born in Rochester, New York, on July 28, 1927. His first major collection, *Some Trees* (1956), showed his familiarity with Renaissance and modern poetry. *The Tennis Court Oath* (1962) reflects the influence of the Surrealism art movement. His other books include *Houseboat Days* (1977), *Shadow Train* (1981), *A Wave* (1984), *Selected Poems* (1985), *April Galleons* (1987), *Flow Chart* (1991), *Hotel Lautréamont* (1993), *Can You Hear, Bird* (1995), *Wakefulness* (1998), *Girls on the Run* (1999), and *Your Name Here* (2000). Bonnie Costello

Ashcan School was a group of American artists of the early 1900's known mainly for their realistic paintings of city life. The group revolted against the traditional, sentimental subject matter then fashionable in American art. It helped establish realism as an acceptable art style in the United States. The Ashcan School consisted of Arthur Bowen Davies, William Glackens, Robert Henri, Ernest Lawson, George Luks, Maurice Prendergast, Everett Shinn, and John Sloan.

The Ashcan School was originally called *The Eight.* It was formed by Henri in 1907 in New York City to oppose the conservative exhibition policies of many of New York City's art galleries. In 1908, the group held an exhibit that included paintings by Glackens, Henri, Luks, Shinn, and Sloan. Their works realistically showed city scenes, such as factories, slums, crowded streets, and night life. Critics called the group the Ashcan School because of the "down-to-earth" realistic subject matter. Three members did not paint in a realistic style. Davies painted dreamlike scenes. Lawson was an Impressionist, and Prendergast painted in a partially abstract style.

Sarah Burns

Each of the artists discussed in this article has a biography in *World Book.*

Oil painting on canvas, the Cleveland Museum of Art, Gift of Amelia Elizabeth White

An Ashcan School painting called *Woman's Work* shows a realistic scene of urban life in New York City. John Sloan, one of the group's most important artists, painted the scene in 1911.

Ashcroft, John David (1942-), became attorney general of the United States in 2001. President George W. Bush appointed Ashcroft to the Cabinet post. Ashcroft was a Republican member of the U.S. Senate, representing Missouri, from 1995 to 2001.

After Sept. 11, 2001, when the United States suffered the worst terrorist attack in its history, Ashcroft helped to coordinate a massive investigation to find those responsible for the attack. He successfully pressed Congress for broadened powers for the Justice Department to prevent future attacks. However, he received criticism from people who felt such powers would limit civil liberties.

As a senator, Ashcroft worked on legislation designed to give states control over more government programs. He was a strong advocate for the pro-life cause, which opposes abortion. He supported the idea of limits on the number of terms members of Congress may serve.

Ashcroft was born in Chicago on May 9, 1942. He later moved with his family to Springfield, Missouri, where he graduated from high school. He received a bachelor's degree from Yale University in 1964 and a law degree from the University of Chicago in 1967.

Ashcroft ran for Congress in 1972 but lost. From 1973 to 1975, he served as Missouri state auditor. Ashcroft was Missouri state assistant attorney general in 1975 and 1976 and state attorney general from 1976 to 1985. He served as Missouri's governor from 1985 to 1993. Ashcroft won election to the United States Senate in 1994 but narrowly lost a bid for reelection in 2000.

Jeremy D. Mayer

Ashe, *ash,* **Arthur** (1943-1993), a tennis player, became the first African American to win the U.S. men's national singles championship. He won the title in 1968. In that same year, he played on the winning U.S. Davis Cup

team (see **Davis Cup**). In 1975, he became the first black man to win the Wimbledon singles championship in England. Ashe retired from competition in 1980.

AP/Wide World
Arthur Ashe

Ashe was born in Richmond, Virginia. His full name was Arthur Robert Ashe, Jr. In 1966, while a student at the University of California at Los Angeles, he won the National Collegiate Athletic Association singles and doubles championships. He wrote a history of black athletes in America called *A Hard Road to Glory* (1987). Ashe died from pneumonia brought on by AIDS. He probably contracted HIV, the virus that causes AIDS, from a blood transfusion. Ashe's memoir, *Days of Grace,* was published in 1993, after his death. Chris Evert

Asheville (pop. 68,889; met. area 225,965) is the economic and cultural center of 18 counties in western North Carolina. It is set in the midst of recreational areas covering more than 1 million acres (400,000 hectares). Asheville is next to Pisgah National Forest and serves as the eastern gateway to Great Smoky Mountains National Park. The scenic Blue Ridge Parkway passes nearby the city (see **North Carolina** [political map]).

Asheville's chief manufactured products are electric switches, glass, synthetic textiles, tools, and wood products. The city serves as the agricultural wholesale center for the surrounding area.

Author Thomas Wolfe was born and raised in Asheville. The boarding house his mother ran, called "Dixieland" in his novel *Look Homeward, Angel* (1929), is open to the public. Asheville-Buncombe Technical Community College and a branch of the University of North Carolina are in the city. Asheville was incorporated as a town in 1797. It is the seat of Buncombe County and has a council-manager government. Jerry L. Surratt

Ashgabat, *ASH guh BAHT* (pop. 407,000), is the capital of Turkmenistan. Ashgabat, also called Ashkhabad, lies in an oasis in the Karakum desert in southern Turkmenistan (see **Turkmenistan** [map]). An earthquake destroyed much of Ashgabat in 1948. The city was rebuilt with low buildings. The Karakum Canal supplies the city with water from the Amu Darya, a river more than 450 miles (724 kilometers) away in eastern Turkmenistan. Irrigation ditches called *aryks* line both sides of roads in Ashgabat. Economic activities in Ashgabat include carpet, textile, metal, and glass manufacturing.

Ashgabat was founded in 1881 as a military outpost for the Russian Empire. It was called Poltoratsk from 1919 to 1927. Already a regional center, Ashgabat became the capital of Turkmenistan in 1924, when Turkmenistan was made a republic of the Soviet Union. It remained the capital after Turkmenistan became an independent nation in 1991. Nancy Lubin

Ashkenazy, Vladimir (1937-), a Soviet-born pianist and conductor, ranks among the finest piano soloists of his generation. He gained fame for the warmth and delicacy of his style. Ashkenazy has been praised for his interpretation of such Russian composers as Sergei Prokofiev, Sergei Rachmaninoff, and Alexander Scriabin. He also specializes in the piano music of Ludwig van Beethoven, Johannes Brahms, Frédéric Chopin, Franz Liszt, Franz Schubert, and Robert Schumann.

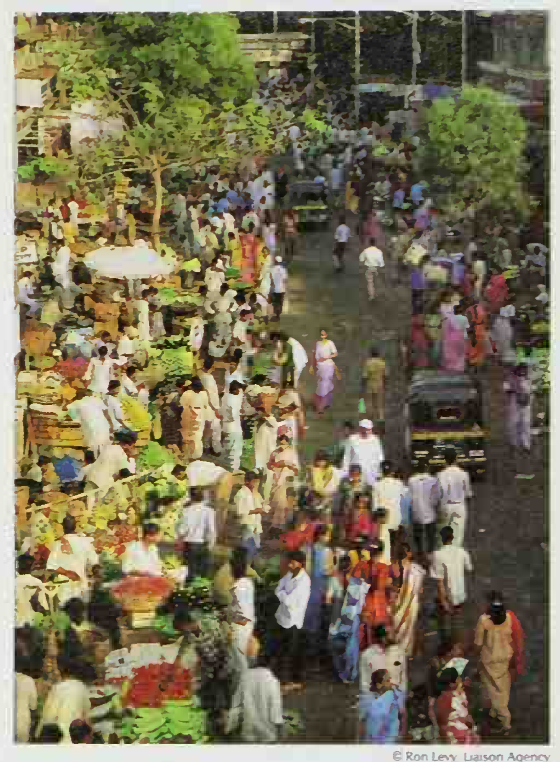
Ashkenazy was music director of the Royal Philharmonic Orchestra in London from 1987 to 1994 and principal guest conductor of the Cleveland Orchestra from 1987 to 1994. Since 1989, he has been music director of the German Symphony Orchestra Berlin (formerly the Berlin Radio Symphony Orchestra). In 1998, he became director of the Czech Philharmonic.

Vladimir Davidovich Ashkenazy was born in Gorki in the Soviet Union (now Nizhniy Novgorod, Russia). He made his performing debut when he was 8 years old and attended the Moscow Conservatory. Ashkenazy married Thorunn Johannsdottir, an Icelandic pianist, in 1961. He left the Soviet Union in 1963 and lived in England until 1968, when he settled in Iceland. He became an Icelandic citizen in 1972. John H. Baron

Ashoka, *uh SHOH kuh* (?-232 B.C.), ruled the Mauryan Empire from about 272 B.C. until his death. Under his rule, the empire covered much of what are now Afghanistan, Bangladesh, India, and Pakistan.

In 261 B.C., Ashoka conquered Kalinga, a region on the east coast of India. After he saw the bloodshed his conquest had caused, Ashoka declared that he was filled with sorrow and regret. He rejected war as a way of gaining political power. Ashoka had many public announcements inscribed on rocks, stone pillars, and cave walls. His inscriptions recommended Buddhist ideals as the highest moral code, but also urged toleration of all peoples and beliefs. He instructed his officials to preach religion and obedience to his laws. He also sent diplomats and Buddhist missionaries to Ceylon (now Sri Lanka), Egypt, Greece, Persia, and Syria. Michael H. Fisher

See also **Mauryan Empire**.



Ashton, Sir Frederick (1904-1988), was an English *choreographer* (creator of dances). His gracious, refined, and tasteful dances helped establish today's English national style in classical ballet.

Ashton was born in Guayaquil, Ecuador. In 1935, he joined the Vic-Wells Ballet as a choreographer. In 1963, he became director of the company, now known as the Royal Ballet. He retired from the position in 1970, but continued to choreograph occasionally. Ashton's major works include *Façade* (1931), *Symphonic Variations* (1946), *Ondine* (1958), and *A Month in the Country* (1976). He was knighted in 1962. Dorothy Lourdou

Ashtoreth. See **Astarte**.

Ashurbanipal, *AH shoor BAH nee PAHL,* also spelled *Assurbanipal,* was the last great king of the Assyrians. During his reign (668-627 B.C.), Assyria became a leading world power. His empire included Babylonia, Persia, Syria, and Egypt. But it was also during his reign that Assyria's power began to decline. In 651 B.C., the Assyrians were expelled from Egypt. A civil war with Babylonia further weakened his empire, even though Assyria won the war in 648 B.C. Ashurbanipal was a dreaded warrior and a great patron of the arts. At his royal palace, he gathered a huge collection of Sumerian, Babylonian, and Assyrian writings. This famous library of clay tablets, now mainly in the British Museum, is the best guide to Mesopotamian history. Norman Yoffee

Asian street scenes offer glimpses of the continent's wide variety of cultures. Some Asian cultures have preserved many traditional ways as they prosper and progress. At an open-air market in Delhi, India, *left,* women dress much as their ancestors did. Other Asian cultures have readily adopted Western-style clothing and architecture, as seen in Tokyo, Japan, *right.*

Asia

Asia is the largest continent in both size and population. It covers almost a third of the world's land area and has about three-fifths of its people. Asia extends from Africa and Europe in the west to the Pacific Ocean in the east. The northernmost part of the continent lies within the frozen Arctic. But in the south, Asia ends in the steaming tropics near the equator.

Asia has some of the world's longest rivers, largest deserts, and thickest forests and jungles. The highest and lowest places on the earth are in Asia. Mount Everest, the highest, rises 29,035 feet (8,850 meters) above sea level along the Nepal-Tibet border. The Dead Sea shore, the world's lowest land, lies about 1,310 feet (399 meters) below sea level between Israel and Jordan.

The 50 countries of Asia include some of the world's largest and smallest countries in population. China, the world's most populated nation, has more than 1 $\frac{1}{4}$ billion people. But about one-third of Asia's countries have populations of less than 5 million people.

Asia also contains some of the world's largest and smallest countries in area. Russia, which lies partly in Europe but mostly in Asia, is the world's largest country in area. It covers more than 6 $\frac{1}{2}$ million square miles (17 million square kilometers). But three Asian nations—Bahrain, the Maldives, and Singapore—each cover less

Chapman, Professor of Human Geography at Lancaster University; Richard Louis Edmonds, Senior Lecturer at the University of London and Editor of The China Quarterly; *Abraham Marcus, Director of the Center for Middle East Studies at the University of Texas at Austin; and Jonathan Rigg, Reader in Geography at the University of Durham.*

Facts in brief

Area: 16,992,000 mi² (44,008,000 km²). *Greatest distances*—east-west, about 6,000 mi (9,700 km); north-south, about 5,400 mi (8,690 km). *Coastline*—80,205 mi (129,077 km).

Population: *Estimated 2002 population*—3,799,971,000; density, 224 per mi² (86 per km²).

Elevation: *Highest*—Mount Everest, 29,035 ft (8,850 m) above sea level. *Lowest*—shore of the Dead Sea, about 1,310 ft (399 m) below sea level.

Physical features: *Chief mountain ranges*—Altai, Elburz, Himalaya, Hindu Kush, Karakoram, Kunlun, Qilian, Qin Ling, Stanovoy, Tian Shan, Yablonovyy, Zagros. *Chief rivers*—Amur, Brahmaputra, Euphrates, Ganges, Huang, Indus, Irrawaddy, Lena, Mekong, Menam, Ob, Salween, Tigris, Xi, Yangtze, Yenisey. *Chief deserts*—Gobi, Karakum, Kyzylkum, Rub al Khali, Taklimakan, Thar.

Number of independent countries: 50.

than 300 square miles (780 square kilometers).

The nations of Asia have a variety of political systems. Communist governments rule China, North Korea, and Vietnam. Such nations as Bhutan and Saudi Arabia have kings. Sheiks control Bahrain, Qatar, and the United Arab Emirates. Asian nations that operate under democratic principles include India, Israel, and Japan. Military leaders have taken control of many Asian countries in times of trouble.

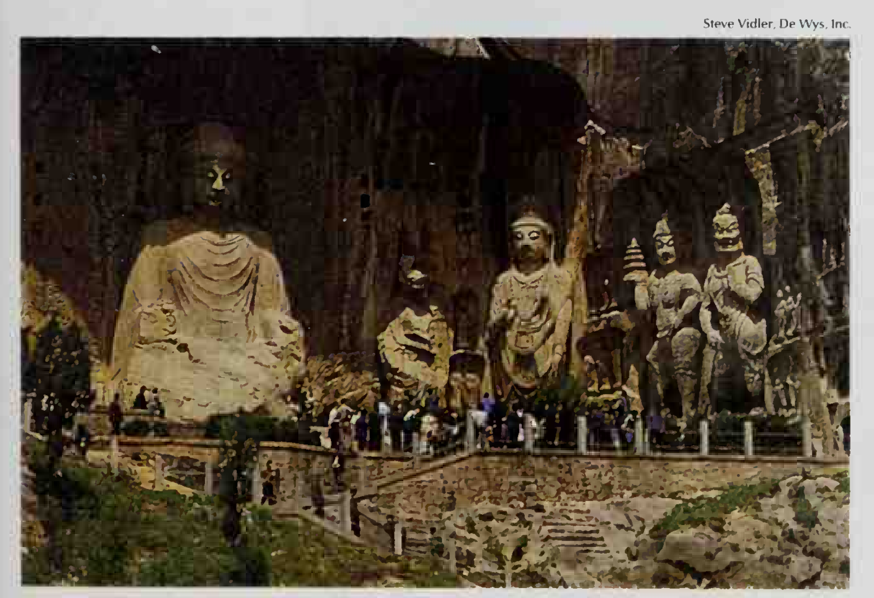
The people who inhabit Asia are as varied as everything else about the continent. The people differ greatly in their ancestry, customs, languages, religious beliefs, and ways of life. Because of these differences, this article discusses the life of the people of Asia in six separate *Way of life* sections.

Civilization in Asia began about 5,500 years ago, long betore it began in Europe. During ancient and medieval times, Asia moved ahead of Europe in economic, cultural, and scientific development. Asians founded the first cities, set up the first systems of law, and became the first farmers and merchants. Asians invented writing and created the earliest literatures. All the world's major religions originated in Asia. In addition, Asians invented paper, the magnetic compass, and movable type.

About A.D. 1500, Europe entered a period of rapid economic and technological progress. As a result, Western European nations became wealthier than their Asian counterparts. What had been European trading outposts in Asia gradually turned into colonies. About 1750, Western European nations began conquering large parts of Asia.

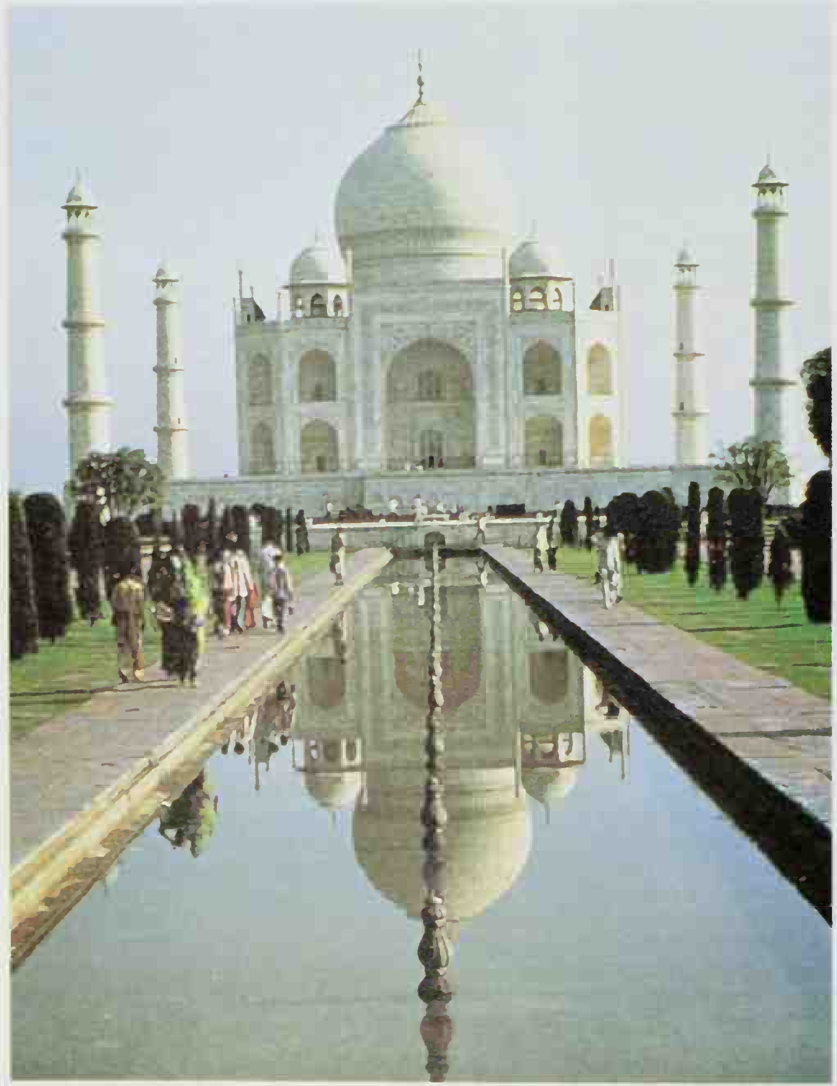
The economic gap between Asia and the West widened during the period of European colonial rule. Europeans and North Americans developed the factory system of manufacturing, and they began to use farm machinery and other aids to agriculture. These developments in industry and agriculture helped create new jobs and increase production, and living standards improved. Most countries in Asia, in contrast, developed little mechanized industry. They remained largely agricultural countries, and their farmers continued to use hand tools and old-fashioned farming methods.

Meanwhile, a population explosion sent the number of people in both Asia and the West soaring. The growing populations created a need for more food, jobs, schools, and other necessities. The West, because of its more advanced economic development, was better able than Asia to handle the problems caused by the growth in population. Today, the population explosion continues throughout Asia, though it has slowed dramatically in Europe and North America.



Almost all colonial Asia gained independence during the mid-1900's. Ever since, many Asian nations have worked to raise living standards by increasing industry, improving agriculture, and slowing population growth. Political disputes in Asian nations have added to the difficulty of this challenge.

After World War II (1939-1945), Asia became a center of the struggle between Communist and non-Communist countries. In many Asian nations, fighting broke out between a government supported by Western allies and Communists trying to replace it. The Communists succeeded in China and Vietnam, and achieved partial success in Korea.



Tensions remain high between the Communists and their democratic rivals in some places. The non-Communist Chinese Nationalists escaped to the island of Taiwan. Today, China and Taiwan struggle over the issue of Taiwanese independence. Korea was divided into Communist North Korea and democratic South Korea. The two sides never signed a formal truce, and a 20-mile (32-kilometer) zone of separation still divides them.

In addition, disputes unrelated to the struggle between Communists and non-Communists have brought about fighting between many groups of people in Asia. Most notably, India and Pakistan have never resolved which country controls the territory of Jammu and Kashmir. As a result of such disputes, Asia almost continually faces wars and threats of wars while trying to solve all its other problems.

Taj Mahal, in Agra, India, is the tomb of an Indian ruler and his wife. The magnificent marble structure is an example of Islamic architecture, which is seen in many parts of Asia.

People

About 3 $\frac{4}{5}$ billion people, or about 60 percent of the world's population, live in Asia. China has more people than any other country in the world, and India has the second largest population. Nearly two-fifths of all the people in the world live in these two countries.

This section gives a broad overview of the population distribution in Asia. It also discusses, in general terms, Asia's *ethnic* (cultural) groups, religions, and languages. The article's six *Way of life* sections provide more detailed information about Asian peoples who live in various regions of the continent.

Population distribution. If Asia's people were distributed evenly throughout the continent, there would be only 224 persons per square mile (86 per square kilometer). But many areas are so cold, so hot, so dry, or so mountainous that few people live there. The vast majority of Asians live in river or mountain valleys or near seacoasts, where many of them live by farming or fishing.

Parts of Asia rank among the world's most thickly populated areas. They include Bangladesh, the Hong Kong peninsula in China, Singapore, eastern mainland China, the Ganges Valley of India, most of Japan, and the island of Java in Indonesia. In these regions, millions of people pack the big cities. Even many rural areas in these places have hundreds or thousands of people per square mile or square kilometer.

Peoples of Asia. The peoples of Asia have rich and varied cultures and ancestries. Asia has dozens of ethnic groups—both large and small. A single country may have several groups. The largest ethnic groups on the continent include the Arabs of Southwest Asia and the Chinese of East Asia.

The members of an ethnic group may be united by language, religion, common ancestry, or other characteristics. Ethnic groups establish rules of conduct for their members and preserve artistic, religious, and

Emil Schulthess, Black Star

The land of North Asia is snow covered and frozen for much of the year. The people of Siberia, in North Asia, raise reindeer for food, clothing, and transportation.

other traditions. Many members of ethnic groups feel a strong sense of identification or belonging.

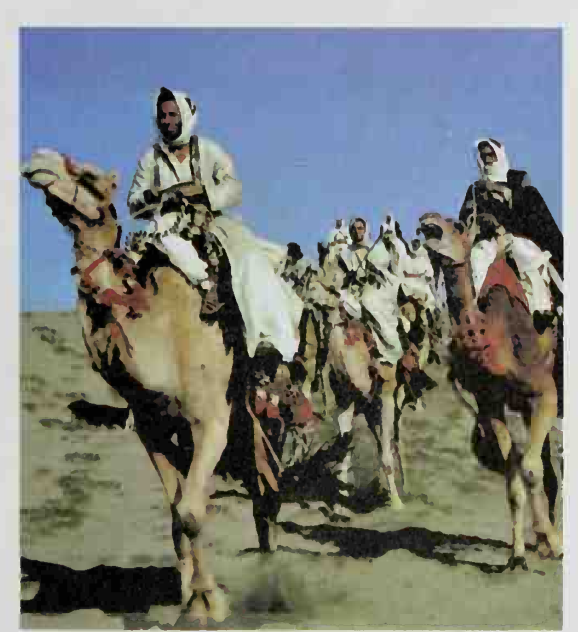
In many parts of Asia, however, neighboring ethnic groups dislike and distrust each other. These feelings often lead to violence among ethnic groups, both within and between countries. During the 1900's, for example, ethnic fighting in Asia included wars between Arabs and Jews, Greeks and Turks, Hindus and Muslims, Chinese Malaysians and Malays, and Armenians and Azerbaijanis. Fighting between the various ethnic groups in Asia strains relations among many countries. Such fighting also causes a lack of unity within some nations.

Religions. All the world's major religions began in Asia—Buddhism, Christianity, Confucianism, Hinduism, Islam, and Judaism. The history of these religions is traced in separate articles and in the **Religion** article.

More Asians practice Hinduism than any other religion. Hinduism is the major faith in India and Nepal.

Islam has the second largest number of Asian followers. Geographically, it ranks as the most widespread religion on the continent. Most of the people of Southwest Asia and Central Asia are *Muslims* (followers of Islam). A majority of Indonesians also practice Islam.

Buddhism is the chief religion of Southeast Asia and also has many followers in East Asia. Lamaism, a branch of Buddhism, is the chief religion of Mongolia and other parts of Central Asia. Confucianism and Taoism also have many followers in China, and Shinto is important in Japan. Many Asian people combine Buddhism with one or more of these other beliefs.



Christianity, which has more followers throughout the world than any other religion, has never been a major faith in Asia. Most people in Cyprus and the Philippines and many in Lebanon, Armenia, Georgia, and Russia practice Christianity. Judaism is the chief religion in only one nation—Israel.

Languages. The many languages and *dialects* (local forms of languages) spoken in Asia present a major barrier to communication. In some parts of the continent, the people of one village cannot speak to their neighbors in a village a few miles away. For example, in Madhya Pradesh, one of India's states, the people speak more than 375 languages and dialects.

Many experts group all languages into nine major language families. Languages of all these groups except African have wide use in Asia.

Arabic and Hebrew, the chief languages of far southwestern Asia, belong to the Afro-Asiatic family. Russian and the chief languages of Afghanistan, northern India, Iran, Pakistan, and Sri Lanka are—like English—Indo-European languages. The major languages of southern India are in the Dravidian family. Languages of the Uralic and Altaic families are spoken in Kazakhstan, Mongolia, Siberia, Turkey, Turkmenistan, and Uzbekistan. Chinese is the major language of the Sino-Tibetan family, which also includes Burmese, Lao, Thai, and Tibetan.

Such southeastern Asian languages as Khmer and

Sid Latham, Photo Researchers

In much of Southwest Asia, the climate is hot and dry, and large areas of land are sandy desert. Many Arabs in the region use camels to carry them over the shifting sands of the desert.

Vietnamese are in the Mon-Khmer family. Most people on the islands in Southeast Asia speak Malayo-Polynesian languages, including Indonesian, Malay, and Filipino. Japanese and Korean make up a language family. See **Language** (Language families; map).

Way of life in Southwest Asia

Southwest Asia covers about 2,700,000 square miles (7,000,000 square kilometers), or 16 percent of the continent. It includes the 7 nations of the Arabian Peninsula and 12 nations north and east of the peninsula.

Saudi Arabia, which is the region's largest nation in size, covers about two-thirds of the Arabian Peninsula. The other peninsular nations are Bahrain, Kuwait, Oman, Qatar, the United Arab Emirates, and Yemen. The nations that lie outside the peninsula include Afghanistan, Armenia, Azerbaijan, Cyprus, Georgia, Iran, Iraq, Israel, Jordan, Lebanon, Syria, and Turkey. Small parts of Azer-

Where the people of Asia live

More people live in Asia than on any other continent. This map shows where they live and where the largest Asian cities are located. The heavily populated areas are shown in the darkest color. Most of the people live in areas where the climate is favorable and the land is suitable for farming.

Deserts—like this one in Kuwait—cover much of Southwest Asia. These dry lands are difficult to farm, but much oil lies under them. Income from oil raises living standards and helps modernize the region. But many nomads still follow traditional ways of life, and, like their ancestors, travel the deserts with their animals.

John Lewis Stage, Photo Researchers

baijan, Georgia, and Turkey are in Europe, but these countries lie mainly in Asia. Southwest Asia also includes the Sinai Peninsula, which is the northeast corner of the African country of Egypt; the disputed region known as the Gaza Strip; and the West Bank, a region west of the Jordan River and the Dead Sea. The Gaza Strip and the West Bank are administered partly by Israel and partly by the Palestinian Authority.

Desert covers much of Southwest Asia. Little rain falls, and water is scarce in most of the region. Even so, many Southwest Asians work on farms. The farmers live crowded together along the seacoasts and in river and mountain valleys, which have enough water for growing crops. The region's deserts are thinly populated. Southwest Asia has a population density of only 104 persons per square mile (40 per square kilometer).

A shortage of good farmland and a lack of big industrial cities in most of Southwest Asia have made economic progress difficult. But the land—even the desert—holds hope for the future. It yields huge quantities of oil, the region's most valuable natural resource. Southwest Asian governments use some of the oil income to fight poverty. They also work to increase farm production and to bring industry to their nations.

The people. About 282 million people, or 7 percent of all Asians, live in Southwest Asia. Members of the Arab ethnic group make up the majority of the population in 11 of the 19 Southwest Asian nations. These 11 nations are the 7 of the Arabian Peninsula, plus Iraq, Jordan, Lebanon, and Syria. The millions of Arabs throughout Southwest Asia and North Africa are united by language (Arabic), religion (Islam), and cultural and historical background.

The first Arabs lived on the Arabian Peninsula and in nearby areas in ancient times. The Islamic prophet Muhammad was an Arab who died in A.D. 632. His followers spread Islam, the Arabic language, and the Arab way of life to many lands.

Israel, most of whose people are Jews, lies among the Arab nations. Like the Arabs, Jews have lived in Southwest Asia since ancient times. Through the years, many Jews settled in Europe, North America, and other parts of the world. In the late 1800's, Jews began a movement to reestablish a homeland in Southwest Asia. This movement led to the founding of Israel in 1948. The Arabs opposed the creation of a Jewish nation in what they considered Arab land. Ever since, the Arabs and Israelis have quarreled—and fought. Conflicts have also erupted between various Muslim groups and between Muslims and Christians. Southwest Asia remains one of the world's chief trouble spots.

The Arabs and Jews speak languages in the Semitic group of the Afro-Asiatic language family. Arabs speak Arabic, and Jews speak Hebrew. People in the countries of northern Southwest Asia—Afghanistan, Armenia, Azerbaijan, Cyprus, Georgia, Iran, and Turkey—speak Indo-European and Turkic languages. The ancestors of the Afghans, Azerbaijanis, Iranians, and Turks came mainly from Central Asia. The Armenians and Georgians are descended from ancient peoples of the Caucasus Mountain region. About 80 percent of the people on the island of Cyprus are Greeks, and Turks make up the other 20 percent of the island's population.

Religions. Christianity, Islam, and Judaism began in Southwest Asia. Today, the majority of people in most of the Southwest Asian nations practice Islam. However, Christianity is the chief religion of Armenia, Cyprus, and Georgia. Judaism is the chief religion of Israel.

Country life. About a fourth of Southwest Asia's people work on farms. Also, thousands of nomads move through the deserts and mountains of Asia herding camels, goats, and sheep. Most of the farmers and nomads follow ways of life that have roots deep in the past. Many people wear clothing similar to that of their ancestors. For example, many Arab men wear long, flowing robes and a draping cloth that covers the head and neck (see **Arabs** [Clothing]).

Like their ancestors, most of the farmers do not own the land they work. Instead, they rent it from wealthy landlords. They use hand tools, and many raise only

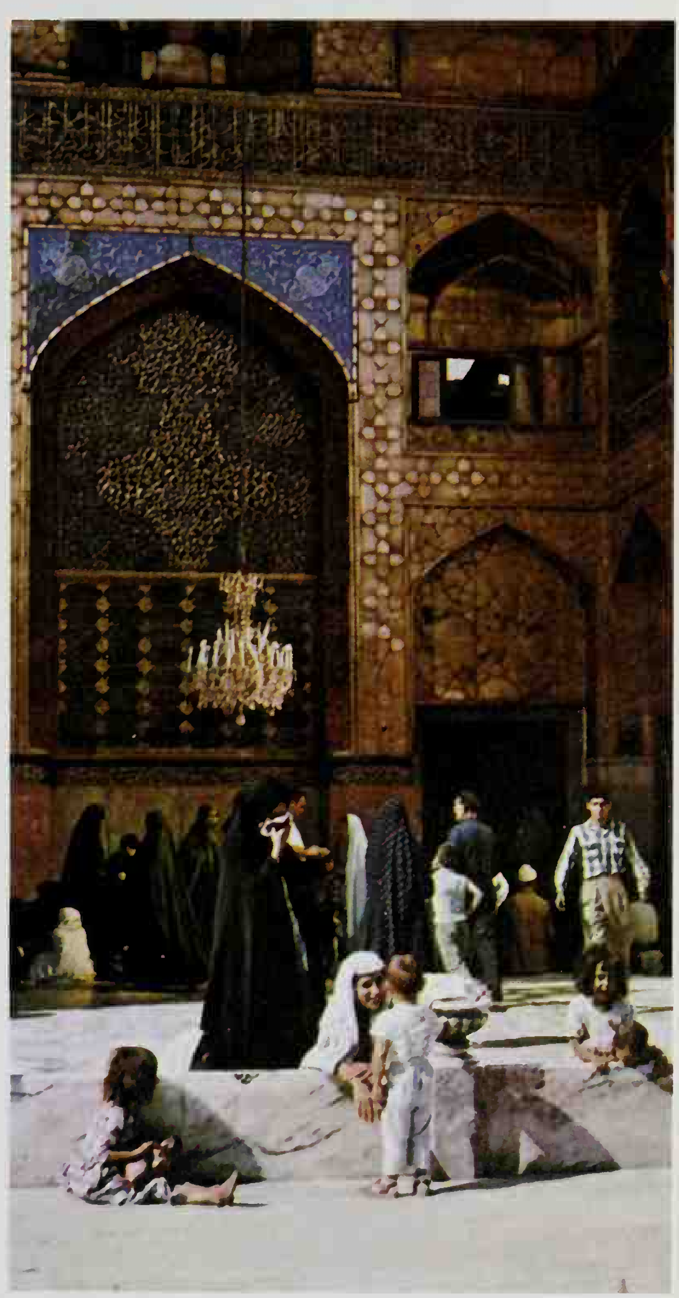
enough food for their families. Farm families eat foods made from such grain crops as barley and wheat. Other important foods include dates, olives, and other fruits.

Some Southwest Asian farmers live on the outskirts of urban areas. Many others live in small villages near the land they work. A typical village consists of about 50 houses crowded together along narrow streets. Dried mud and adobe are the most common building materials. Some villages have a public bathhouse, and a teahouse where men gather to discuss community affairs. But many villages have only one public building—a *mosque* (Islamic house of worship).

Southwest Asian nomads rely almost entirely on their animals for the necessities of life. They live in tents made from camel or goat hair. Their food includes cheese, meat, and milk, all of which come from their animals. Many nomads make their clothing from animal hair and skins. The nomads move about, looking for pasture for their herds. Occasionally—perhaps once a year—a nomad visits a city or town to sell cheese, meat, skins, and wool and to buy supplies. The number of nomads has declined as many have settled in villages and towns, sometimes under pressure from their governments.

Many rural Southwest Asian women—especially Arab women—remain at home most of the time, as their female ancestors did. These women both keep house and take part in outdoor chores, such as harvesting crops or milking animals. When they appear in public, they cover their faces with a veil.

Social relationships in rural Southwest Asia are also based on traditions. Most farm and nomad families live according to an ancient arrangement called the *extended family.* Grandparents, parents, unmarried children, and married sons and their families all live together. The oldest male in the family holds authority over the other family members. The oldest male also has the responsibility for the well-being of the entire group.



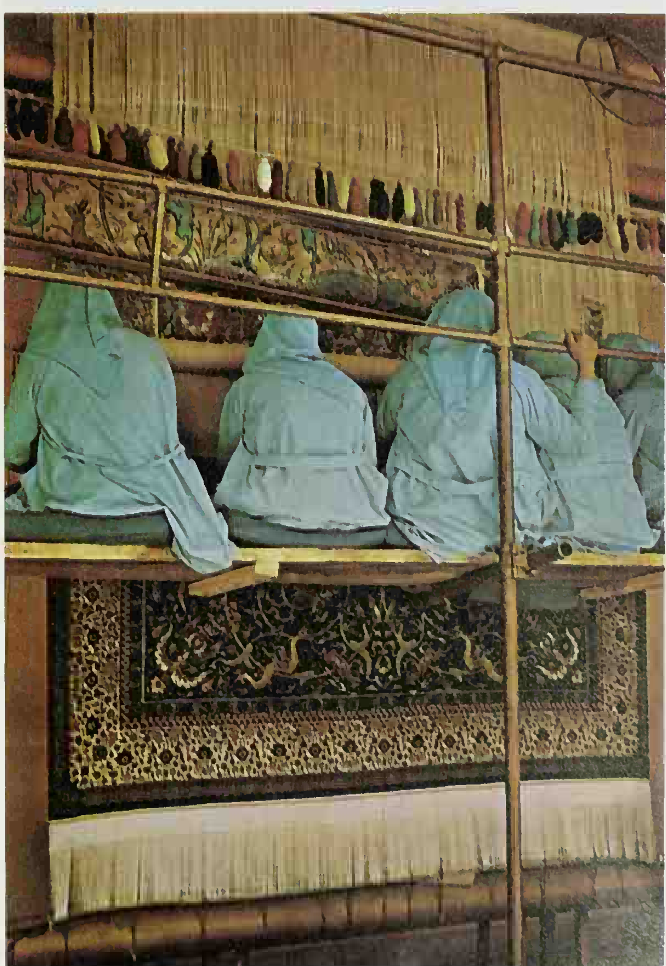
Outside the family, a farmer's strongest ties are to the village, and a nomad's are to the tribe. A chief and a council of elders govern most villages. These officials settle disputes between families. Most nomad tribes consist of many families related on the male side. The tribal leader, called a *sheik* in Arab nations, is usually the wealthiest member of the group. The leader settles disputes between families and often provides aid for needy members of the tribe.

Many farmers and most nomads have little or nothing to do with their national government. They view government officials as outsiders without power in village or tribal matters. Many Southwest Asian governments are working to establish more contact with their rural people. In some areas, the governments teach modern agricultural techniques to farmers. They have also established schools in a number of rural communities, helping to bring in ideas about modern life.

In rural Southwest Asia, radios and televisions have become more common. In these remote corners, however, people must use satellite dishes to receive TV signals beamed from satellites high above the earth.

Rural life in Israel differs greatly from that in other nations of Southwest Asia. Many Israeli farmers live in a collective community called a *kibbutz,* in which the farmers share all property and combine their labor. Other Israeli farmers belong to a cooperative community called a *moshav.* On a moshav, the farmers purchase equipment and other goods as a group. However, the farmers own their own land and homes. See **Israel** (Agriculture).

City life. Since the 1950's, the cities of Southwest Asia have grown tremendously. The three largest cities of Southwest Asia are Baghdad, Iraq; Tehran, Iran; and Istanbul, Turkey. However, most of the city of Istanbul lies



Sammy Abboud, FPG

Muslims make up the largest religious group in most Southwest Asian nations. A Muslim's religious life centers around a house of worship called a *mosque.* Some mosques, including this one at Meshed, Iran, are famous for their beautiful decorations.

in Europe. Riyadh, Saudi Arabia, is the largest city of the Arabian Peninsula. There are more urban people than rural people in each of the countries of Southwest Asia except Afghanistan and Yemen.

Many Southwest Asian cities present a sharp contrast between the old and the new. They include an old section, which dates back hundreds of years, and a modern section. The old sections have long been trading centers where farmers, nomads, and merchants exchange goods and where craftworkers make and sell handcrafted articles. Much of this activity takes place in crowded trading and shopping centers called *bazaars* or *suqs.* Some of these are open-air markets, while others are covered and resemble shopping malls. The covered bazaar in Istanbul, which was built in the mid-1400's, contains more than 4,000 shops. The houses in the old sections are small and jammed tightly together. Old sections of Muslim cities feature beautiful houses of worship called *mosques.*

Photographic Library of Australia

Skilled craftworkers in Southwest Asia produce a variety of goods that are prized by people in many parts of the world. These craftworkers in Jordan weave an Oriental rug, a kind of rug that is valued for its high quality and beauty. The rug has elaborate designs, for which Islamic art is famous.

The modern sections of Southwest Asian cities resemble modern Western cities in many ways. Tall apartment and office buildings rise along wide streets. These sections also include airports, motion-picture theaters, and radio and television stations. Some cities have industrial plants, such as factories and oil refineries.

Social changes have also come to the cities of Southwest Asia. New jobs have opened up for business people, factory workers, government workers, physicians, teachers, and others. Most of the governments have expanded their school systems to train people for new job opportunities. The extended family has become much less common in the cities than in rural areas. In addition, the city people have stronger ties with their national government than do the rural people.

Women in cities have more freedom than do women in rural areas. In most countries, old customs—such as wearing a veil in public—have been challenged. In Iran and Saudi Arabia, however, conservative Muslims continue to enforce old customs.

Education. The *literacy rate* (percentage of people over 15 years old who can read and write) is low in much of Southwest Asia. Several Southwest Asian nations have a literacy rate of less than 50 percent. But the literacy rate varies widely from country to country. In Armenia, Azerbaijan, Georgia, and Israel, almost all adults can read and write.

Throughout history, most Southwest Asian children received little or no schooling. Boys learned a craft, farming, or herding from their fathers, and girls learned housekeeping skills from their mothers. But during the mid-1900's, most Southwest Asian nations built many new schools, especially in the cities. Today, most city children attend school for at least a few years. More children than ever go on to a college or technical school. Educational progress has been much slower in rural Southwest Asia than in the cities.

The arts. The best-known art of Southwest Asia is Islamic art. This term refers to an art style developed by the Arabs and adopted by the many peoples they conquered. Islamic art flourished from the mid-700's to about 1700 and then declined.

Architectural works—especially mosques—rank as the most famous examples of Islamic art. Islamic artists also created beautiful bookbindings and illustrations, ceramics, glassware, metalware, rugs, textiles, and sculptures. Islamic religious leaders prohibited artists from depicting human beings and animals. Instead of drawing people and animals, artists developed a style of decoration that consisted of elaborate patterns of winding stems, leaves, and other objects. See **Islamic art**.

Many Southwest Asian decorative artists, including potters and rug makers, still use the traditional Islamic style. But authors have modernized Southwest Asian literature. In the past, most authors wrote about life among the nobility and royalty. Today, however, many writers deal with life among the common people of Southwest Asia.

Way of life in South Asia

South Asia covers about 1,730,000 square miles (4,480,000 square kilometers), or 10 percent of the continent. India occupies almost three-fourths of this region, and Pakistan makes up almost one-sixth. Pakistan bor-

A South Asian farmer gets advice from a government farm expert. In an effort to reduce the widespread poverty that exists in their countries, South Asian governments try to teach farmers about new seeds and fertilizers and improved agricultural methods. This scene is in India, South Asia's largest country.

WORLD BOOK photo

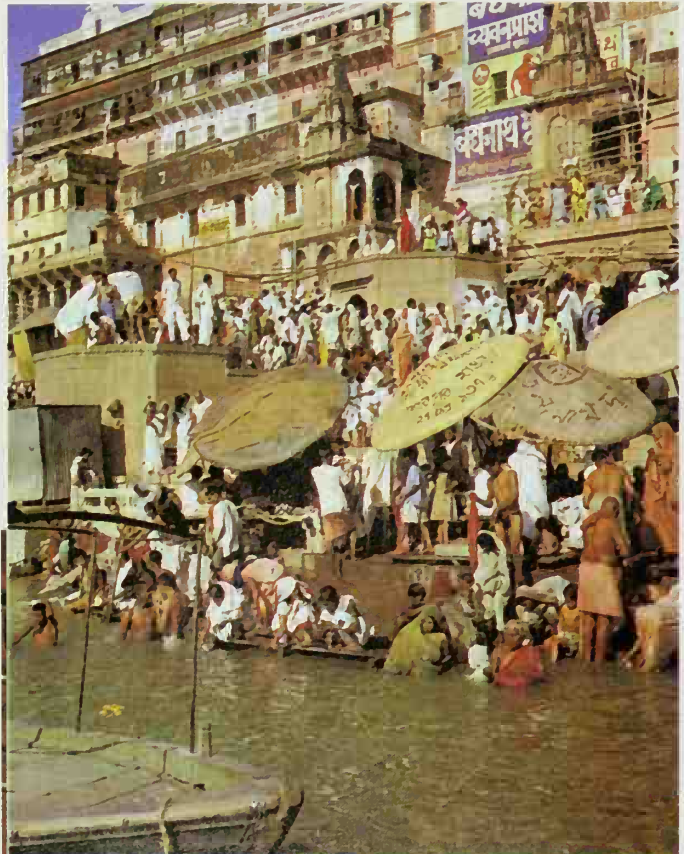
ders India to the northwest. South Asia also includes five small nations. These nations are Bangladesh, along India's eastern border; Bhutan and Nepal, high in the mountains along India's northeast border; and Sri Lanka and the Maldives, island countries that lie south of India in the Indian Ocean.

South Asia ranks among the world's most crowded places. About 1 $\frac{1}{3}$ billion people live there—about a third of all Asians and a fifth of all the people in the world. The region's population density of 790 persons per square mile (305 per square kilometer) is more than 7 times the world average. South Asia's chief farm area, the northern plains of India, is as crowded as many cities. Kolkata, a city in India, has about 110,000 persons per square mile (42,000 per square kilometer). Dhaka, the capital of Bangladesh, has about 74,000 persons per square mile (29,000 per square kilometer).

South Asia has much fertile farmland, and there are several large cities with thriving economies. Even so, the region faces severe poverty. The South Asian nations are trying to solve this problem by improving agricultural techniques and by creating new jobs in the cities. However, the rapid growth of population in the overcrowded region makes the fight against poverty much more difficult.

The people. Over 75 percent of South Asia's people live in India. More than 10 percent live in Pakistan, and almost 10 percent in Bangladesh. The four other countries of South Asia contain the remaining 3 percent of the population.

India's two largest groups are the Indo-Aryans and the Dravidians. Most of the Indo-Aryans live in northern India. The majority of the Dravidians live in the south. The ancestors of the Indo-Aryans invaded India from Central Asia about 1500 B.C. These people are known as the Aryans. The Aryans conquered the Dravidians in northern India and drove some of them south.



The many groups that make up Pakistan's population include people of Afghan, Arabic, Aryan, Dravidian, Persian, and Turkish origin. Other South Asian peoples include the Sinhalese of Sri Lanka and of the Maldives, whose ancestors came from northern India. The Tamils of Sri Lanka are descendants of people from southern India. The Nepalese have ancestors who include both Aryans and people from Tibet and Mongolia.

The people of South Asia are divided along the lines of religion, language, and social class. Differences between Hindus and Muslims—the region's two major religious groups—have often caused violence. These differences even led to the creation in 1947 of a new nation, Pakistan. In an attempt to end the bloodshed between Hindus and Muslims, the United Kingdom, which then controlled India, divided it into two nations—India for Hindus and Pakistan for Muslims. East Pakistan became the independent nation of Bangladesh in 1971.

Language differences also have far-reaching effects among the people of South Asia. Most states of India, for example, consist chiefly of people who speak the same language. The Indian government changed state boundaries and created new states to give certain language groups their own states. See India (Languages).

In general, social class divides people throughout South Asia. Social standing, however, probably has the greatest importance among the Hindus of India, who make up a majority of South Asia's population. Each Hindu belongs to a social class called a *caste*. India has about 3,000 castes. Hindus belong to their parents' caste and find it hard to join a higher caste. Each caste in India has its own customs. These customs limit social contact with members of other castes. Marriage between members of different castes seldom occurs. For more detailed information about the caste system in India, see Caste; India (Religion).

Religions. About four-fifths of India's people are Hindus, and more than a tenth are Muslims. Most of the people of Bangladesh, the Maldives, and Pakistan are Muslims. Sri Lanka has a mixture of Buddhists, Christians, Hindus, and Muslims. In Nepal, about 90 percent of the people are Hindus, and most of the others are Buddhists. About two-thirds of the people of Bhutan are

T. S. Satyan, Black Star

Hindus bathe in the Ganges River at Varanasi, India. Hindus consider the Ganges River sacred. They believe they purify themselves spiritually by bathing in its waters.

WORLD BOOK photo

An Indian schoolroom is used by two groups of children at the same time. The teacher instructs older children in writing while younger children play with educational toys.

Buddhists, and a majority of the rest are Hindus.

As India's chief religion, Hinduism has the most followers in South Asia. Hinduism—unlike Christianity, Islam, and Judaism—is not based on the belief in a single, personal god. A Hindu may believe in many gods, all of whom are different forms of Brahman, the Supreme World Soul or Spirit. Hindus believe all living creatures have a soul whose goal is to become united with Brahman. After death, a soul in one body passes on to another body. This process continues until the soul becomes perfect enough for union with Brahman.

Country life. About three-fourths of the people of South Asia live in villages and work on nearby farms. The majority of South Asian farmers own a small piece of land, but some rent land from wealthy landlords.

Some farms in South Asia employ modern agricultural tools and methods, but many of the farmers still use the same kinds of hand tools and farming methods as their ancestors used hundreds of years ago. Large numbers of South Asian farmers must struggle just to raise enough to feed their own families. Most South Asian farm families include not only several children but also the other members of an extended family.

South Asians get most of their food from rice, wheat, millet, barley, and other grains, and from such vegetables as beans and peas. Many Hindus eat no meat. They believe all animals have a soul and must not be killed. See India (Food and drink).

The clothing worn by rural South Asians varies from region to region. Many people wear a large piece of cloth wrapped around the body. Women's garments of this kind are called *saris*. Some men cover their heads with a turban. See India (Clothing).

The houses of a typical South Asian village stand close together. Most of them are small and made of sun-dried bricks or mud. A wall surrounds each house in many villages, giving the people extra privacy.

There is much contact between rural and urban South Asia. Government officials from the cities often go to villages to teach the people how to use modern fertilizers, plows, and seeds. They help villagers set up health clinics and schools. The government also builds roads and irrigation systems in rural areas.

The struggle to improve the people's lives faces many difficulties. South Asian governments lack great wealth. But even if they had much wealth, they would be hard-pressed to end poverty as long as the population keeps growing so quickly. In addition, many rural South Asians are proud of their customs and traditions and feel reluctant to change the way they live and work. However, the economic growth and modernization of urban areas holds promise for the future of the region.

City life. Although South Asia is chiefly a rural region, it has many large cities. Delhi, Kolkata, and Mumbai in India and Karachi in Pakistan rank as the biggest cities. Several other cities in India and Pakistan also have more than a million people.

Few places present so sharp a contrast between old and new—and between the wealthy and the poor—as do the cities of South Asia. The British built some parts of these cities during their reign. The United Kingdom ruled most of the region from the late 1700's to the mid-1900's. During this colonial period, British citizens occupied much of the housing in the sections they had built.

South Asian governments continued to build up the cities after the various nations became independent. Today, middle-class and wealthy South Asians, including business people, doctors, government officials, and lawyers, live primarily in the newest sections.

South Asia's cities include many terrible slums. Millions of people in these slums live in cheap, crowded apartments and in shacks made of pieces of metal, wood, or cloth. The slums in some cities are so crowded and poverty is so widespread that thousands of people have nowhere to live at all. They sleep in doorways, on sidewalks, or in any other place they can find.

South Asian governments are trying to improve city life as well as rural life. Their efforts include slum clearance and construction programs to provide more decent housing. They also sponsor programs to expand industry and provide more jobs—and to train unskilled workers for those jobs. But the cost of improving any city is high, and the problems are many. In South Asian cities, as in many cities elsewhere, high birth rates rank among the major problems. Also, thousands of rural people move to the cities each year in search of a better life. Many end up no better off than they were before.

Education. Over 85 percent of Sri Lanka's adults can read and write. But the other countries in the region have low literacy rates. Large numbers of children never go to school at all, either because no school is nearby or because they must work to help support their families.

Since the mid-1900's, the South Asian governments have built many new schools. More children now attend school than ever before, and literacy rates are improving. But the governments have found it difficult to build enough schools and to train enough teachers to serve their enormous populations.

T. S. Satyan, Black Star

Whirling Bhutanese dancers perform in colorful costumes. Dance ranks among South Asia's major arts. The highly symbolic movements in the dances tell stories, usually religious ones.

The arts. South Asia has a rich and varied artistic tradition. The Aryans produced outstanding literature long before the time of Jesus Christ. Numerous Aryan literary works contributed to the development of Hinduism. Such writings included the epics the *Mahabharata* and the *Ramayana* and the philosophical works called the *Vedas* and the *Upanishads*. The Aryans composed their works in Sanskrit, the first Indo-European language with a literature. See **Sanskrit language; Sanskrit literature.**

Three religions—Buddhism, Islam, and Hinduism—had major effects on the arts of South Asia. Major Buddhist works include many beautiful sculptures of Buddha, founder of the religion. The Muslims made their major contribution in the field of Islamic architecture. A giant tomb in this style, the magnificent Taj Mahal, is one of the world's most beautiful buildings. See **Taj Mahal**, and the pictures of the building in this article and in the **India** article. The Hindus built stone temples, many of which are richly decorated with sculptures of gods.

Other important arts in South Asia include dance and music. The highly symbolic movements in South Asian dances tell stories and are included in many dramas. South Asian music sounds strange to many Western people because it uses a different scale than does music of the West. South Asian people play much of their music on stringed instruments, such as the lute, sitar, and vina. The flute and the *tabla*, a type of drum, are also important instruments.

During the colonial period, the British introduced some forms of Western art—including Western architecture and the novel—into South Asia. Many South Asians came to fear that their own artistic traditions were being forgotten. During the 1900's, they began calling for a return to South Asian art forms. Today, the art of the region shows the influence of both traditional South Asian art and Western art.

A reversal of the West's influence on South Asian culture occurred during the mid-1900's. At that time, South Asian art and philosophy began to attract many people in the West. Sitar music, a physical and mental exercise called *yoga*, and Hindu religious teachers called *gurus* became especially popular. The attraction to South Asian culture was most widespread among young people of the West.

Way of life in Southeast Asia

Southeast Asia covers about 1,570,000 square miles (4,070,000 square kilometers), or 9 percent of the continent. The area has an average of 336 persons per square mile (130 per square kilometer)—about three times the world average. The region includes the peninsula east of India and south of China, and thousands of islands south and east of the peninsula.

Eleven independent nations make up most of Southeast Asia. Five of these nations—Cambodia, Laos, Myanmar, Thailand, and Vietnam—are located on the peninsula. Malaysia lies partly on the peninsula and partly on the island of Borneo. Brunei also lies on Borneo. Indonesia and the Philippines each consist of thousands of islands, and Singapore is made up of approximately 50 islands. East Timor takes up about half of Timor Island, the rest of which is part of Indonesia. Geographers con-

Fields of rice—like these in Indonesia—cover a large part of the Southeast Asian countryside. Southeast Asia has much fertile soil and plenty of water from rivers and rainfall. The soil and water are natural resources that help farmers in the region grow large amounts of rice and other agricultural products.

Herta Newton, Van Cleve Photography

sider far eastern Indonesia to be part of Oceania rather than part of Asia.

Southeast Asia has a wealth of natural resources. Forests cover much of the land, valuable minerals lie beneath it, and fish are plentiful in the coastal waters. Much of the soil is fertile, and the rivers and rainfall provide plenty of water.

Europeans had established trading outposts in Southeast Asia as early as the 1500's. In the 1700's, Europeans began taking control of Southeast Asia. By the late 1800's, only Thailand remained free of European rule. Many Southeast Asians resented colonialism and fought for independence. These nations began to win independence after World War II ended in 1945.

Most of the newly independent Southeast Asian governments faced uprisings by Communists and other groups who wanted to take over the countries. Communists gained control of North Vietnam in 1954. In 1975—after years of bitter fighting—they took over South Vietnam, Cambodia, and Laos. The Vietnamese Communists reunited North and South Vietnam into the single nation of Vietnam in 1976. For details on the conflict in Vietnam, see Vietnam War.

The people. More than 525 million people, or 14 percent of all Asians, live in Southeast Asia. Most live in rural areas, but millions live in large, crowded cities.

The ancestors of most Southeast Asians came to the region from Central Asia and southern China during prehistoric and ancient times. They drove the original inhabitants of the region into the mountains and other remote areas. Today, descendants of the original inhabitants live in those remote areas. Through the years, thousands of people from China and India settled in Southeast Asia. These people control much of the region's business activity.

Fighting has taken place within and between nations in Southeast Asia, especially as groups there have battled over control of the best land. Through much of the 1900's, political differences caused sharp divisions among Southeast Asians. In almost all the countries, Communists tried to take political power from non-Communists. In some cases, the Communists succeeded. The fighting in and between Southeast Asian nations divided the people and stalled economic progress.

Beginning in the 1980's, relations between Southeast Asian nations—both Communist and non-Communist—markedly improved. By 2000, all of the nations of the region belonged to an economic and political organization known as the Association of Southeast Asian Nations (ASEAN).

Religions. Buddhism is the chief religion on the peninsula. It teaches that people can find peace and happiness by getting rid of their desires. Many Southeast Asians, partly because of their religious beliefs, seem easygoing to people in the West—and to their Chinese and Indian neighbors.

Islam began in Arabia and spread all the way to Southeast Asia. Today, it ranks as the chief religion in Indonesia, Malaysia, and Brunei. Christianity became the major faith of the Philippines during the period of Spanish rule, and it remains so today.

Many Southeast Asians, especially rural people, mix religious beliefs and practices with *animism,* the belief that everything in nature has a spirit. These people believe that good and bad spirits cause good and bad fortune. Some farmers offer small sacrifices to the spirits in the hope that the spirits will bring good fortune and not harm them. Some of these farmers build small boxes resembling birdhouses on the tops of poles in their rice fields. In the boxes, they put cloth, food, incense, paper, and other offerings to the spirits.

Country life. The majority of Southeast Asians live in small villages and work on farms. Many Southeast Asian farmers, like farmers elsewhere in Asia, use ancient agricultural methods. They plant by hand and harvest with sickles and other hand tools. Many use water buffaloes to pull large, rakelike tools that plow the fields. However, the use of farm machines, such as tractors, is becoming more common. Rice is the major crop and chief food throughout most of Southeast Asia.

A typical farm village in this region has from 25 to 30 houses, made mostly of bamboo and wood. Many rural Southeast Asians build their houses on raised platforms for protection against insects, wild animals, and heavy rains. The space under the platforms provides shelter for household animals. Almost all villages on the Southeast Asian peninsula include a pagoda or some other Buddhist shrine.

The clothing of Southeast Asia varies widely. People of Western countries are perhaps most familiar with the cone-shaped hats worn by many farmers and the colorful *sarongs* (skirts) of the Indonesians. Many Southeast Asians, though, have adopted Western-style clothing.

Some Southeast Asians, especially islanders, work on large plantations owned by the government or wealthy landowners. The plantations produce large quantities of coffee, copra, fruits and vegetables, palm oil, rubber, sugar cane, tea, and tobacco. Most of these products go for export.

Most of the mainland farmers own a small plot of land. Much of the land is fertile and, in good times, almost all the farmers can raise enough food to feed their families. Many have food left over that they sell. Some have begun raising cash crops, such as cashews, cotton, and jute.

In general, farmers on the peninsula are better off than those on the islands. Good farmland is scarce on the islands, and a large number of farmers work on land that is owned by others.

Rural Southeast Asians maintain the custom of extended family. But compared to Southwest Asia and South Asia, relationships between older and younger generations fall into less rigid patterns.

Hermann Schlenker, Photo Researchers

A Buddhist monk in Thailand collects money from people at a religious celebration. He hangs it on a money tree. Buddhism is the major religion on the Southeast Asian peninsula.

City life. All the nations of Southeast Asia have at least one big city, and some nations have several. Jakarta, Indonesia, and Manila, in the Philippines, are the largest cities in the region.

Southeast Asian cities serve as centers of government and manufacturing and as links between the rural areas and the rest of the world. Farm products, lumber, minerals, and other goods go from the rural areas to the cities to be shipped abroad. Goods from other countries pass through the cities before being sent on to the rural areas. Manufacturing takes place in many of the region's cities. The largest cities, such as Singapore and Manila, have much large-scale manufacturing.

Outsiders have long played important roles in Southeast Asian cities. In the 1800's, Chinese and Indian immigrants began taking over a large part of the retail trade in the cities. Today, in some countries, they are still retail leaders. The European colonial rulers also established businesses and governments in the cities. They gained wealth for themselves and their nations from Southeast Asia's resources. They also built up the cities and modernized them along European lines.

Southeast Asians continued the modernization process after becoming independent. Many of the cities have luxury hotels, high-rise apartment and office buildings, motion-picture theaters, and other modern features. But like cities everywhere, they include slums and other run-down areas.

Education varies widely in Southeast Asia, but the region as a whole has a high literacy rate. Since independence, the governments of some countries have established many new schools and set up special programs to increase literacy. Indonesia has raised its literacy rate from less than 10 percent in 1945 to more than 80 percent today.

The arts. Precolonial Southeast Asian art reveals much Indian and some Chinese influence. A large part of the art is religious and includes many Buddhist shrines and statues of Buddha. Colonial rule brought Western architecture and literary forms to the region.

The art of Indonesia and Malaysia shows less outside influence. The people on the islands of Bali and Java, in Indonesia, have unique and highly developed styles of architecture, dance, drama, and music. Their dances, in which each movement helps tell a story, are probably their most famous art form. See **Indonesia** (Arts).

Way of life in East Asia

East Asia covers about 2,570,000 square miles (6,640,000 square kilometers), or 15 percent of the continent. The region includes most of China, the world's largest nation in population. Tibet, Qinghai, and Xinjiang, three thinly populated parts of western China, are in Central Asia.

China covers more than 90 percent of East Asia, and it has about 85 percent of East Asia's people. Four other nations—Japan, North Korea, South Korea, and Taiwan—are also part of East Asia.

About $1\frac{1}{2}$ billion people, or about 40 percent of all Asians and a fourth of all the people in the world, live in East Asia. The region is one of the world's most crowded places. The population density of East Asia, 594 per-

Chinese farmers work together on a collective farm. The Chinese Communists established collective farms after they took over China in 1949. China covers more than 90 percent of East Asia's land and has about 85 percent of its people.

Emil Schulthess, Black Star

sons per square mile (230 per square kilometer), is over five times the world average.

Off and on throughout history, China has ruled much of East Asia. The Chinese influence spread through the places they ruled and even to areas they did not rule. Chinese art strongly influenced art throughout East Asia. People throughout the region adopted Chinese religious and philosophical beliefs to some degree.

The Confucian system of ethics is probably the most important Chinese contribution to everyday life in East Asia. This system teaches the duties and manners of rulers and subjects toward each other, of family members toward one another, and of friends toward friends. The Confucian system stresses polite behavior and obedience to proper authority, two lasting characteristics of East Asian society.

The influence of China brought some unity to life in East Asia. But the region has been sharply divided along political and economic lines. China and Japan, East Asia's two largest nations, have almost completely opposite political systems. A Communist government rules China, and the people have little political freedom. Japan operates under democratic principles of government, and its people have much freedom.

China's economy has centered on agriculture and remains largely underdeveloped. As China has moved away from strict government control of the economy, its standard of living has improved. Japan ranks among the world's main industrial nations and practices more advanced agriculture than any other country in Asia. The Japanese have one of the world's highest standards of living.

Political differences divide China and Taiwan and also North Korea and South Korea. The Chinese Communists drove the Chinese Nationalists out of China in 1949. The Nationalists then established their government in Taiwan. Before World War II broke out in 1939, North Korea and South Korea were one country. Today, Communists rule the north, and non-Communists govern the south. Troops have patrolled both sides of the border between North Korea and South Korea since the two countries fought each other during the Korean War (1950-1953).

The people. The first East Asian civilization began in China. Today, descendants of the early Chinese—known as the Han ethnic group—make up a majority of China's people, except in the far north and west. Han people also form a majority in Taiwan. The Koreans are an ancient people who have often come under Chinese rule. People called the Ainu were among the first inhabitants of the islands that now make up Japan. But almost all of the people of Japan today are descended from Asian peoples who settled the country about 2,000 years ago.

Religions. The Chinese government has worked hard to discourage religion. However, many of the people still practice the traditional religion of their country. This religion—Buddhism combined with teachings of Confucianism and Taoism—is also the chief faith in Taiwan. Many Koreans practice Buddhism, but their religion also shows Confucian influences. Buddhism and Christianity rank as the leading religions in South Korea. The North Korean government also discourages religion, even more strongly than China's government. Buddhism and Shinto are Japan's major faiths, and many Japanese combine the two. Confucianism influences religion in Japan, as elsewhere in East Asia.

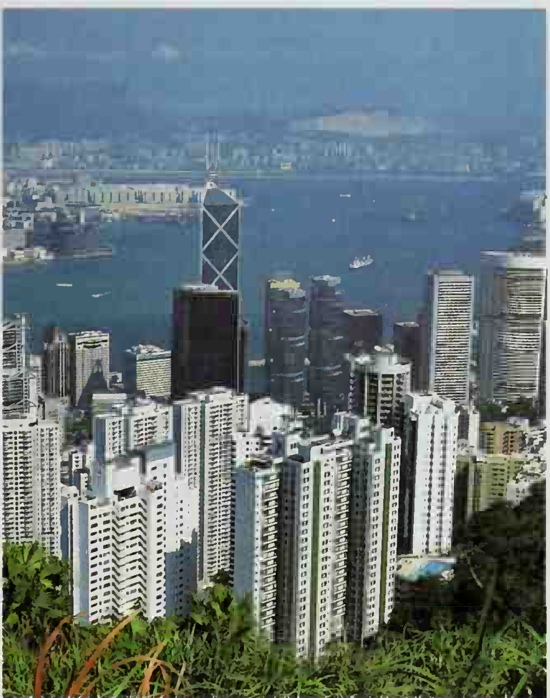
Life in China. China has many large cities, including about 35 with a population of 1 million or more. Even so, it has always been an agricultural nation. About half of the people work on farms.

Most Chinese farm families live in two- or three-room houses. These homes are made of mud or clay brick and have a roof of tile or straw. Many city dwellers live in large apartment buildings. However, other city residents live in crowded apartments above stores or behind workshops. Still others live in old neighborhoods where the houses resemble those in rural areas. The Chinese eat mainly vegetables and various foods made from rice, wheat, and other grains.

Only about 4 percent of China's people belong to the

Communist Party. However, the party has almost complete control of the country—and it has the power to order sweeping changes in the people's way of life. In the early 1980's, for example, the Communists decreed that each married couple should have no more than one child. They hoped to limit China's population growth by this measure. Other major Communist goals include the elimination of social classes and the modernization of China's economy. See China (Way of life).

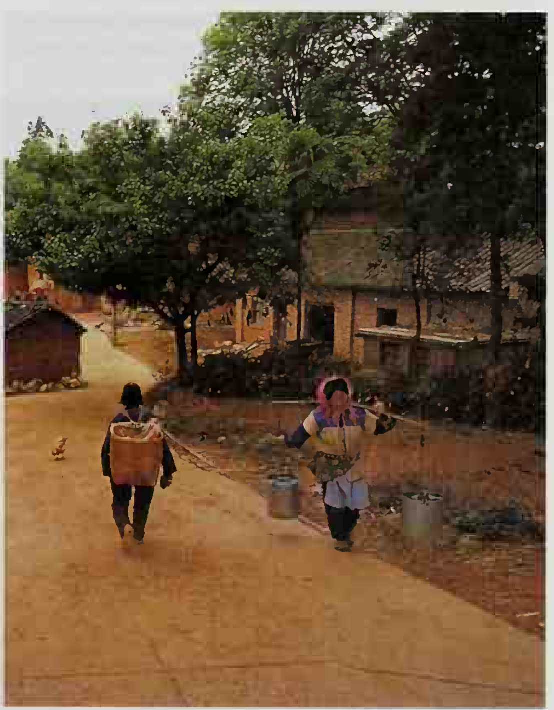
Property. After the Communists came to power in 1949, they took over most businesses and factories in China. They also completely changed the ownership of agricultural land. Before the Communists gained control of the country, many Chinese farmers owned a small plot of land. Others worked on large farms owned by wealthy landlords. During the 1950's, the Communists *collectivized* China's agriculture—that is, they organized the peasants into groups who owned and farmed the land cooperatively.



In the 1980's, the Chinese government shifted emphasis away from collective farming. Individual families began farming more of the land. Initially, the families were required to give part of their crop to their collective and to sell a quota of farm products to the government at a fixed price. They then sold their surplus for profit at a market. The government has gradually relaxed its requirements. Now many farm families are free to raise and sell crops as they choose. In addition, the government encourages families to establish small businesses, such as stores, repair shops, and restaurants. The government still owns many large businesses, however.

Family life has always been important in Chinese society. In pre-Communist China, *extended families* were widespread. In such families, the oldest male had complete authority. Husbands ruled their wives, and parents had total control over their children. Today, most family units consist only of parents and children, though some also include grandparents. Relationships within families have become much less rigid. Husbands and wives treat each other as equals, and parents no longer expect their children to show unquestioning obedience.

In pre-Communist days, relatively few women worked outside the home. Today, nearly all adults have a job. In many families, a grandparent cares for the children during the day. Many other children stay in day-care centers while their parents work.



Social class. Confucian teachings gave the Chinese a respect for educated people. In pre-Communist China, a group of scholars who served as government officials ranked just below the emperor and his family in social importance. To become a scholar-official, a person had to learn Confucian philosophy thoroughly and pass difficult civil-service examinations. Other well-educated Chinese, including doctors, lawyers, and teachers, also had high social rank. The Communists, despite their own control over society, teach the principle of *equalitarianism.* According to this principle, all people, no matter what their occupation, have equal social rank. In practice, though, some groups of people—such as government officials—have much more power, wealth, and prestige than others.

The economy. China has long been one of the world's poorest nations. The country has much good farmland, and it ranks among the leading producers of many

Rural houses in China are built of mud bricks, clay bricks, or stone. The majority of the Chinese people work on farms and live in rural villages, such as this one in Yunnan Province.

crops. But China has such a large population that it struggles to raise enough food for everyone.

The Communists hope to eliminate poverty in China through the modernization of the country's agriculture and industry. Chinese agricultural production has increased, but most farmers still use crude hand tools and farming methods. The Communists have greatly increased industrial production. But further growth will depend on China's acquiring new technology and training highly skilled workers and technicians.

Life in Japan differs greatly from that in most of the rest of Asia. Japan is a modern country in every sense of the word. More than 75 percent of its people live in urban areas. Japan's big cities are busy centers of commerce and industry. Tokyo, the capital of Japan, is one of the world's largest cities. Tokyo is also the chief city in the heavily populated Tokyo-Yokohama urban area.

Manufacturing makes Japan an industrial giant and does much good for Japan's economy. However, manufacturing also helps cause a problem faced by all industrial nations—pollution.

Japan's farms also reflect a modern way of life. Almost all Japanese farmers own their land. The use of chemical fertilizers, farm machinery, and other advanced agricultural methods is more common in Japan than anywhere else in Asia. The success of modern farming methods, however, has forced many Japanese farmers to seek part-time work outside the farm.

The Japanese, more than any other Asian people, have adopted features of Western life, especially American life. For example, baseball ranks as Japan's favorite sport, and neon signs light up many city streets. Most people in Japan wear Western-style clothing. Some Japanese, especially older people, wear the traditional *kimono* (loose robe) at home and for special occasions.

The Japanese have also kept many old traditions, including their deep respect for beauty. Shinto, once Japan's state religion, teaches love of nature's beauty. Zen, a branch of Buddhism chiefly practiced in Japan, is famous for its emphasis on beauty in even simple things. Long ago, monks in Zen monasteries made art forms of everyday functions, including bathing, flower arranging, gardening, and tea drinking. These and other artistic traditions became—and remain—part of the way of life for people in Japan.

Many people in Japan, including the wealthy, live in a traditional plain, wooden Japanese house. Most of these homes have a garden and a high surrounding wall. Almost every Japanese family that can afford it owns at least one brush painting mounted on a scroll. At many meals, the Japanese serve each food in a separate bowl to emphasize the food's color, shape, and texture. Rice is the chief food. The people eat with chopsticks.

The extended family is not nearly so common in Japan as it was before the 1900's. But the Japanese still have strong family ties and a deep respect for authority. They expect individuals to obey all people who have authority over them, including their father, older brothers, and government officials. At the same time, persons in authority must act courteously toward others. This rule comes from an old belief that one person should never embarrass another.

Economic growth and modernization began in Japan in the mid-1800's. Before that time, Japan's rulers worked to keep the country free from outside influences. The Japanese way of life was rooted deep in the past. Japan ended its isolation when it began trading with the United States during the 1850's. The nation adopted Western economic ways and made itself a world power.

Japan's economic progress suffered a major setback

A Japanese factory produces automobiles that will be exported to countries throughout the world. Factory workers in Japan manufacture a wide variety of goods for export and use at home, helping to provide the Japanese people with one of the highest standards of living in the world.

with the nation's defeat in World War II. But the Japanese, with help from the United States, rebuilt their country and its economy with astonishing speed.

Korea and Taiwan. North Korea modeled its economic, political, and social systems on those of other Communist countries. Rural people, who make up about a third of the population, live on collective farms operated by the government. The country has much industry. Most of the industrial workers live in city apartments and work in factories owned and operated by the government.

South Korea and Taiwan were formerly agricultural countries. Agriculture is still important, but after the 1950's, South Korea and Taiwan developed into industrial nations. Their economies grew rapidly, and living standards rose greatly.

Education. Japan and North and South Korea have high literacy rates. Almost all Japanese 15 years of age or older can read and write. Most Japanese attend elementary school and high school, and a high percentage go on to college. More than 90 percent of adult Koreans can read and write.

In China, the Communists have expanded elementary education. During the 1940's, only a small percentage of the people could read and write. Today, about four-fifths of all Chinese 15 years of age or older can do so. China still has a severe shortage of schools, but the situation is gradually improving. Some children teach their parents or grandparents how to read and write.

The arts. East Asia has one of the world's oldest and richest artistic traditions. The Chinese created artworks before the beginning of written history. Through the years, Chinese artists became masters in many art forms, including architecture, painted porcelain, carving, scroll painting, and sculpture. Much Chinese art shows Buddha or other religious subjects. Chinese artists also portrayed people, animals, and nature, and created beautiful designs and rich colors. Artists in other parts of East Asia combined Chinese styles with their own.

In China today, artists strive for self-expression. But the government discourages art that is critical of Communism. Both Japan and South Korea have continued their rich artistic traditions but have also adopted some Western art forms. For example, the people of both countries enjoy Western plays, television dramas, and motion pictures. Filmmakers in Japan and in Hong Kong, which returned to Chinese control in 1997, produce hundreds of movies yearly, many of which have won international awards.

For more detailed information on East Asian art, see the *Arts* section of the articles on **China** and **Japan**. See also the articles on specific art forms, including **Architecture; Painting;** and **Sculpture.**

Way of life in North Asia

North Asia covers about 5 million square miles (12,900,000 square kilometers), or about 30 percent of the continent. It is the largest region in Asia. It extends from the Ural Mountains to the Pacific Ocean. North Asia consists entirely of Siberia, which makes up about 75 percent of Russia. The rest of Russia lies west of the Urals, in Europe.

North Asia covers more land than any other region in Asia but has the smallest population. About 38 million people live in the region, or about 1 percent of Asia's total. North Asia has a population density of only 8 persons per square mile (3 per square kilometer).

A harsh climate has limited North Asia's development and population growth. The region has an abundance of natural resources, including many minerals, vast oil

C. J. Coulson, Pictorial Parade

A fish market in Pusan, South Korea, operates in a way that is common in many parts of Asia. Sellers display their goods out-of-doors. The customers inspect the goods carefully before buying them. The fishing industry is important and fish markets are common throughout East Asia.

The Trans-Siberian Railroad winds through a bleak and frozen part of North Asia. North Asia is the continent's largest region in area but its smallest in population. Much of the region is undeveloped, partly because of its cold climate. Ice and snow cover most of North Asia about half the year.

Sven-Erik Hedin

fields, rich forests, and grasslands in the extreme southwest that are good for farming. But the winters are long and bitter. Ice and snow cover most of the region about six months of the year. The temperature can drop below −90 °F (−68 °C). Most of the coastal waters, lakes, and rivers freeze for much of the year.

Because of North Asia's isolation, governments, including that of the Soviet Union, have used it as a place of exile and imprisonment. The Soviet Union was formed under Russia's leadership in 1922, and it existed until 1991. Russia and the other former Soviet republics are now independent nations. In the past, Russian and Soviet rulers sent millions of criminal and political prisoners to isolated parts of Siberia. Many prisoners were forced to work building factories, mines, and railroads.

The use of forced labor for Siberian construction projects ended after the death of Soviet dictator Joseph Stalin in 1953. The government then began trying to attract workers to North Asia by offering high salaries and long vacations. However, many workers stay only a few years before leaving for better living conditions elsewhere. During some years, more people leave Siberia than move there.

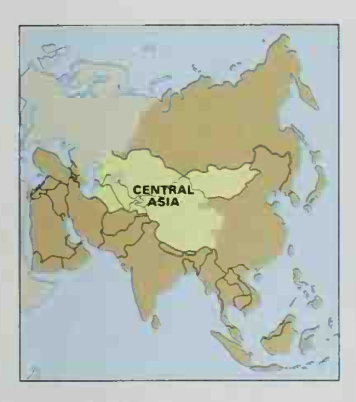
The people. Most Siberians are Russians. Ethnic Russians are descended from Slavs who lived in Eastern Europe several thousand years ago. Such Mongol and Turkic groups as Buryats, Tuvinians, and Yakuts lived in Siberia originally, and descendants of these peoples still live there.

Religion. Russian Orthodoxy, a branch of Christianity, is the chief religion among North Asians of European descent. Many descendants of the original North Asians practice Buddhism or Islam. The Soviet Union's Communist leaders tried to discourage religion, but many people still practiced their faith. In the late 1980's, religious toleration began to increase dramatically, and attendance at religious services shot up.

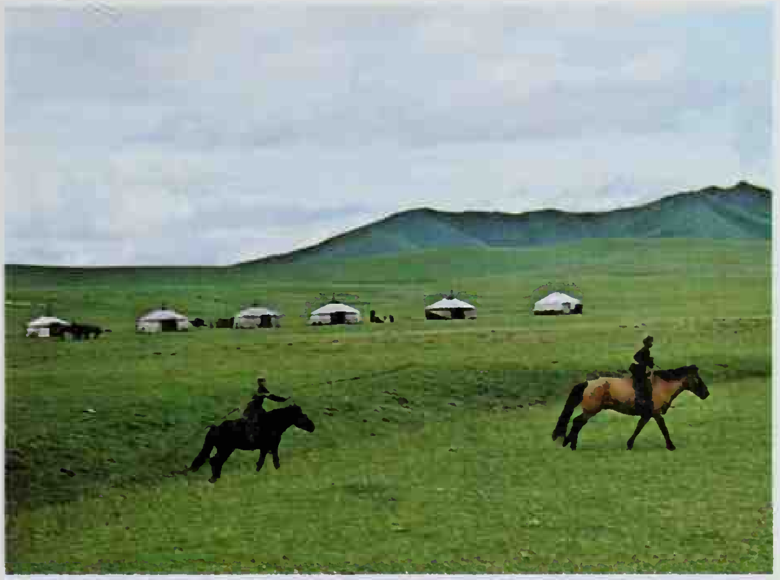
Life of the people. Many North Asians farm, fish, or work in factories or mines. Most North Asian factories operate in cities along the Trans-Siberian Railroad. Until the late 1980's, the Communist government owned or controlled most of the farms and factories throughout the Soviet Union. In the late 1980's, however, the Communists began to allow private ownership. After the fall of the Soviet Union in 1991, most businesses became privately owned.

About 70 percent of Siberia's people live in cities. Most city people are crowded into small apartments. Many people in rural areas live in simple, but more spacious, log houses. Novosibirsk is the largest city in Siberia. It has a population of about 1 ½ million.

Education. Almost all Russians can read and write. Public education is free for all citizens. Children attend school for 11 years, from ages 6 to 17.



The Communist government of the Soviet Union controlled education and considered it a vehicle for social advancement. The government also banned private schools. After the breakup of the Soviet Union, new private schools began to open, and educators removed the emphasis in the school curriculum on Communist Party principles.



The arts. Much art of North Asia shows Chinese and Islamic influence. Some art shows Christian influence.

Way of life in Central Asia

Central Asia covers about 3,486,000 square miles (9,029,000 square kilometers), or 21 percent of the continent. It is the second largest region in Asia. Only North Asia has more land. Central Asia includes Tibet, Qinghai, and Xinjiang, which lie in western China, and the independent nations of Kazakhstan, Kyrgyzstan, Mongolia, Tajikistan, Turkmenistan, and Uzbekistan. A tiny part of Kazakhstan lies west of the Ural River, on the continent of Europe.

Except Mongolia and the Chinese-controlled areas, the lands of Central Asia were once part of the Communist-led Soviet Union, which broke up in 1991. These nations have moved away from the Communist system to democratic forms of government. However, most have retained close ties to Russia, which led the Soviet Union.

Central Asia's grassy plains are the home of many livestock herders. Raising livestock is the major economic activity in Central Asia. In Mongolia, the herders live in tents called yurts. Except for the plains, Central Asia is largely an area of huge deserts and high mountains and plateaus.

George Holton, Photo Researchers

Mongolia adopted a Communist system in 1921. In 1990, it changed to a democratic system. The rest of Central Asia is under Chinese rule. Qinghai is a province of China, which is ruled by a Communist government. China calls Tibet and Xinjiang "self-governing regions," but the Chinese government actually rules them.

Central Asia is a region of high plateaus and mountains, vast deserts, and treeless, grassy plains. Much of the land is too dry or too rugged for farming. A majority of the people earn a living by herding livestock. Industrial activity centers in the region's few cities.

More than 80 million people live in Central Asia, or about 2 percent of the continent's population. Of the regions of Asia, only North Asia has fewer people. Central Asia has a population density of about 24 persons per square mile (9 per square kilometer).

The people. The people of Mongolia are called Mongols. The great conqueror Genghis Khan united various Mongol tribes in the early 1200's. He and his grandson Kublai Khan built the largest land empire in history. It extended from China and Korea, across much of Central and Southwest Asia, and into Europe. The people of Central Asia's other independent nations include the Kazakhs, the Kyrgyz ethnic group, and ethnic Tajiks, Turkmen, and Uzbeks.

Even though Qinghai, Tibet, and Xinjiang are part of China, most of their people are not Chinese. Tibetans make up the population of Tibet, and many of the people of Qinghai are Tibetans. Tibetans have lived in the area since ancient times. Uygurs, a people of Turkic origin, make up about half of Xinjiang's population.

Religion. Most Central Asians are Muslims. Islam is the chief religion in Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, and Uzbekistan. When these areas were part of the Soviet Union, the Communist government discouraged religion, but people continued to practice their faith. These nations now allow religious freedom.

Islam is also the chief religion in the Chinese region of Xinjiang. Lamaism, a branch of Buddhism, is the chief religion in Mongolia, Tibet, and Qinghai. The Chinese Communists discourage religion in the areas under their control. The Chinese government regards religion as superstition. It encourages the people to study science and political thinking, rather than religious beliefs, to solve their problems.

Life of the people. All of Central Asia was once under Communist control. Today, only Qinghai, Tibet, and Xinjiang continue to be ruled by Communists. The six independent nations of Central Asia have moved to democratic forms of government, and they have removed controls that existed in such areas as religion, education, and the arts.

Tashkent, the capital of Uzbekistan, is the largest city in Central Asia. It has about 2 million people. Most city dwellers live in single-story houses or apartment buildings. The majority of the people of Central Asia live in rural areas. Most of them farm or raise livestock.

In much of Central Asia, people in rural areas live in mud-brick houses in villages. Many rural villages do not have electric power or running water. Most families are large, and many members of an extended family may live together in one household. Such a household might include parents, married children and their offspring, and other relatives. Some rural people live in traditional tentlike dwellings called *yurts.* These portable homes are constructed of a circular wooden frame covered with felt.

Many of Mongolia's people live on livestock farms. The farms are like huge ranches with small towns in the center. The central buildings include houses, offices, shops, and medical centers.

In Xinjiang, large numbers of people are herders who live near oases. Many people farm on the oases.

The Chinese Communists seized Tibet in 1950. Before that time, few parts of the world were so completely controlled by religious leaders as was Tibet. Buddhist monks ruled the country and owned most of the land. The monks and a small group of nobles made up Tibet's upper class. Farmers and wandering herders formed Tibet's lower class. The farmers worked the land, and

most nomads tended the flocks of monks and nobles.

The Communists reduced the power and wealth of the monks and nobles. They broke up many large estates and took over the land or distributed it among the people. They reduced the importance of religion. The work of farmers and herders has changed little since the Communist take-over. But the farmers and herders give much of what they produce to the government rather than to landowners.

Life in Mongolia before Mongolian and Russian Communists took over resembled life in Tibet. The monks had religious and political power and great wealth. They owned large herds, which were given to them by the people as offerings. The youngest son of each family was expected to become a monk. The monks and a small group of nobles made up Mongolia's upper class. The lower class consisted chiefly of herders who moved about the country with their flocks.

The Communists established large livestock farms and tried to force herders to settle there. But in the early 1990's, the government allowed herders to leave the large farms. By the end of the 1990's, the livestock herds and most of the agricultural land had come under private ownership.

Education in Mongolia and Tibet centered around religious instruction before the Communists took over. Except for the monks and nobles, few people received more than a few years of schooling. The Communists extended education to more people. Teaching Communist principles is an important part of the curriculum in the Chinese regions of Qinghai, Tibet, and Xinjiang. It also was important in Mongolia until 1990.

In the rest of Central Asia, the Communist government of the Soviet Union once controlled education. Since the breakup of the Soviet Union, schools in the former Soviet republics have removed the emphasis on Communist Party principles from the curriculum. Most of the people in these nations can read and write. Most children attend school for 11 years, from ages 6 to 17.

The arts. Carpet making is an important craft in Central Asia. Other important crafts include embroidery and jewelry making. In Kazakhstan and Kyrgyzstan, the recitation of *epics* (poems about heroic events) is an important part of the culture. In the Chinese regions of Central Asia, the arts, like education, formerly centered around religion but today are intended to serve Communism.

The land

Asia, the world's largest continent, covers about 17 million square miles (44 million square kilometers), or about 30 percent of the world's land area. It extends from the Arabian Peninsula, Turkey, and the Ural Mountains eastward to the Pacific Ocean. From the Arctic Ocean, it reaches south to the Indian Ocean. Geographers consider thousands of islands off the mainland as part of Asia. These islands include—roughly from west to east—Cyprus, the Maldives, Sri Lanka, most of Indonesia, the Philippines, Taiwan, and Japan.

Asia and Europe are part of the same mass of land. No body of water separates the two completely, and so some geographers consider them as a single continent called Eurasia. Certain physical features mark the division between Asia and Europe. The Ural Mountains, Ural River, and Caspian Sea act as an east-west boundary in the north. The Dardanelles, Sea of Marmara, Bosporus Straight, Black Sea, and Caucasus Mountains link to form a north-south border in the west.

Asia has some of the world's highest mountains, largest deserts and plains, most important rivers, and best—and worst—soil. This section describes each land region of Asia. It also tells about Asia's major natural features and how they affect the lives of the people.

Land regions. Asia has six major land regions, as discussed in the *Way of life* sections of this article. Southwest Asia is a land of desert in the south and of mountains and plateaus in the north. Dry soil makes farming difficult in most of the region. But Southwest Asia's land contains much oil, one of the world's most valuable natural resources. The northern border of South Asia includes the Himalaya, the world's highest mountain range. Much fertile soil lies south of the mountains. Southeast Asia is rich in natural resources, including fertile soil, forests, and mineral deposits. East Asia also has much fertile soil and other valuable resources.

Forests cover a large part of North Asia, and areas of good farmland lie in the southwestern section of this region. But much of northern North Asia is so cold that the land stays frozen throughout most of the year. Central Asia has much of the continent's poorest land. Its main features include deserts, mountains, and rocky plateaus.

Mountains. Asia has more mountains than any other continent. The mountains make transportation difficult in many places. They also separate people from each other and have hindered the exchange of ideas. On the other hand, melting ice and snow from mountaintops feed many Asian rivers. Millions of farmers depend on water from these rivers to grow crops.

Many of the major Asian mountain systems branch

Mount Everest, highest place on the earth, towers 29,035 feet (8,850 meters) in the Himalaya range on the Nepal-Tibet border. Other Asian peaks are also over 25,000 feet (7,620 meters) high.

Björn Bölstad, Photo Researchers

The Dead Sea shore, the lowest place on the earth's surface, lies about 1,310 feet (399 meters) below sea level. The shore, *shown here,* is on the border between Israel and Jordan. The land around the Dead Sea is rocky and barren. The sea itself is about nine times as salty as the ocean.

out from a large group of rugged peaks and deep valleys called the Pamirs. This area lies where Afghanistan, China, and Tajikistan meet. It is sometimes called the *roof of the world.* Some peaks in the Pamirs tower over 25,000 feet (7,620 meters) above sea level. The floors of some of the valleys are as much as 4 miles (6 kilometers) below the peaks.

The Tian Shan range extends northeast from the Pamirs into Xinjiang. The Altai Mountains form part of the boundary between Mongolia and Xinjiang. Beyond these high ranges, the smaller mountains of such ranges as the Stanovoy and Yablonovyy reach across southern Siberia toward the Sea of Okhotsk.

The Kunlun Mountains extend east from the Pamirs. This range forms the Qilian Mountains in eastern Tibet, then becomes the Qin Ling range in central China.

The Karakoram Range extends southeast from the Pamirs. The famous Himalaya rises south of the Karakoram Range and extends along Tibet's southern border. The lofty Himalaya includes many of the world's highest peaks. On the border between Nepal and Tibet, Mount Everest—the world's highest mountain—rises 29,035 feet (8,850 meters) above sea level.

The Hindu Kush range extends west from the Pamirs across Afghanistan. Farther west, the Elburz, Zagros, and other ranges enclose the high Plateau of Iran. The Pontic and Taurus mountains surround Turkey's Plateau of Anatolia near the western end of Asia. The Caucasus Mountains extend through southern Russia, Georgia, and Azerbaijan. The Caucasus Mountains form one of the boundary lines between Asia and Europe.

Rivers. Millions of Asians live crowded together in the continent's river valleys and deltas. The rivers play an important role in the lives of the people. Many rivers aid farmers by depositing fertile soil along their courses and providing water for irrigation. They also serve as important transportation routes for trade and travel.

Southwest Asia's major rivers flow through the northern part of the region. The Tigris and Euphrates rivers begin in Turkey and meet in Iraq, forming the Shatt al Arab. The Karun River flows from Iran into the Shatt al Arab, which empties into the Persian Gulf. The Jordan River flows south from Lebanon into the Dead Sea.

In South Asia, several rivers flow south from the mountains in the northern part of the region. The main ones include the Indus, which winds through Pakistan and into the Arabian Sea; and the Brahmaputra and Ganges, which flow through northern India and Bangladesh before emptying into the Bay of Bengal. The *delta,* a low plain formed from sediments, at the mouth of the Brahmaputra and Ganges is the largest river delta in the world.

Four important Southeast Asian rivers begin in the mountains that are in and near Tibet. There, the Irrawaddy, Mekong, Chao Phraya (Menam), and Salween rivers start their long routes through Southeast Asia to the sea.

East Asia's major rivers, the Huang He (Yellow River) and Yangtze, begin in the Tibetan Highlands and flow east across China. The Huang He empties into the Yellow Sea, and the Yangtze empties into the East China Sea. The Yangtze, which measures 3,900 miles (6,275 kilometers) long, is Asia's longest river. The Xi, southern China's chief river, flows from south-central China into the South China Sea.

The major rivers of North Asia—the Lena, Ob, and Yenisey—flow from south to north through northern Siberia. They empty into the Arctic Ocean. The Amur River is the major waterway of far eastern Siberia.

Large parts of Central Asia have no rivers. But important rivers rise in the mountains of that region.

Deserts and plains. Deserts extend diagonally across Asia from the Arabian Peninsula northeast to China and

Mongolia. These huge deserts are unsuitable for farming, and few people live there.

The Arabian Desert makes up most of the Arabian Peninsula. Other deserts cover much of the rest of Southwest Asia. A desert called Karakum occupies most of Turkmenistan. Kyzylkum is a desert that spreads across southern Kazakhstan and northern Uzbekistan. The Thar Desert stretches across much of the border between India and Pakistan. Farther east, the Taklimakan of western China and the Gobi of China and Mongolia form huge wastelands. The frozen tundra region that is in northern Russia is sometimes called a *cold desert* because so few plants can grow there (see Tundra).

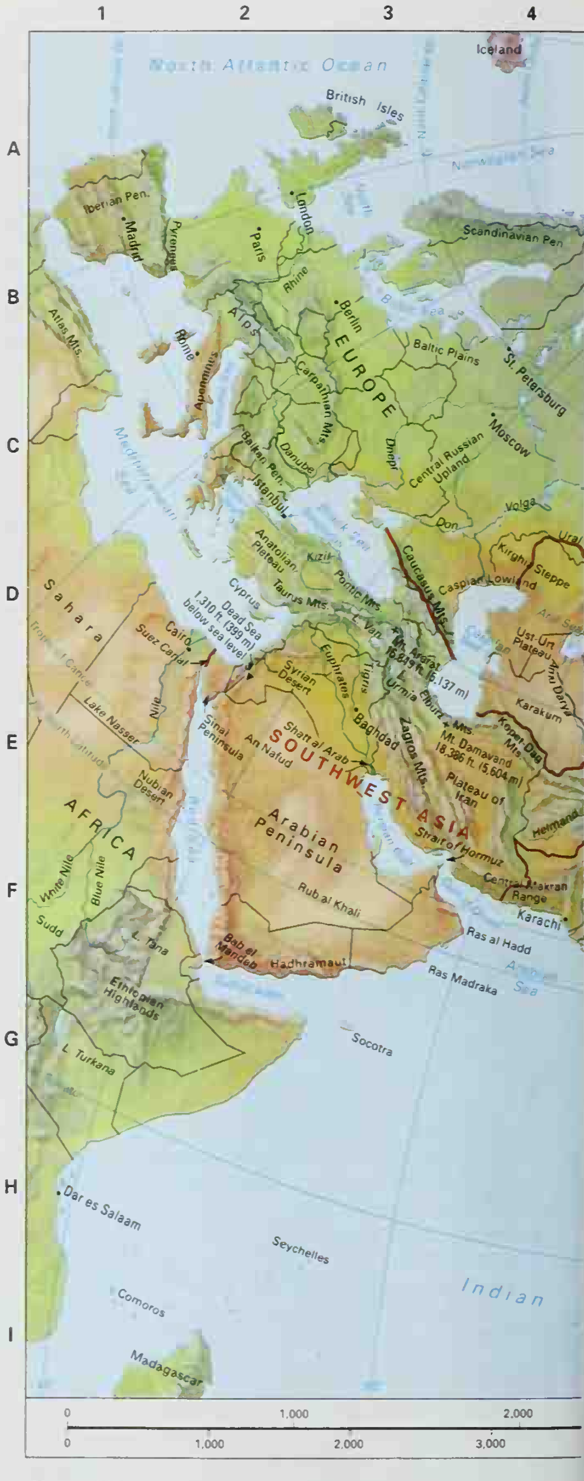
Plains are flatlands. Rivers cut through most plains and rain falls on them, helping make the soil fertile. The major Asian plains include those that lie across northern India, eastern China, northern Kazakhstan, and central Russia.

Coastline, bays, seas, and lakes. Asia's coastline measures about 80,205 miles (129,077 kilometers)—over three times the distance around the earth's equator. Many harbors along the coast are shallow. Through the years, mud and silt carried downstream by rivers have partly filled the harbors. Asia's northern harbors, on the Arctic Ocean, stay frozen much of the year.

Two huge bays of the Indian Ocean indent Asia's southern coast. These are the Bay of Bengal east of India and the Arabian Sea west of India.

Along Asia's east coast, islands and peninsulas block off parts of the Pacific Ocean into a series of seas. These seas include—from north to south—the Bering, Okhotsk, Japan, Yellow, East China, and South China seas.

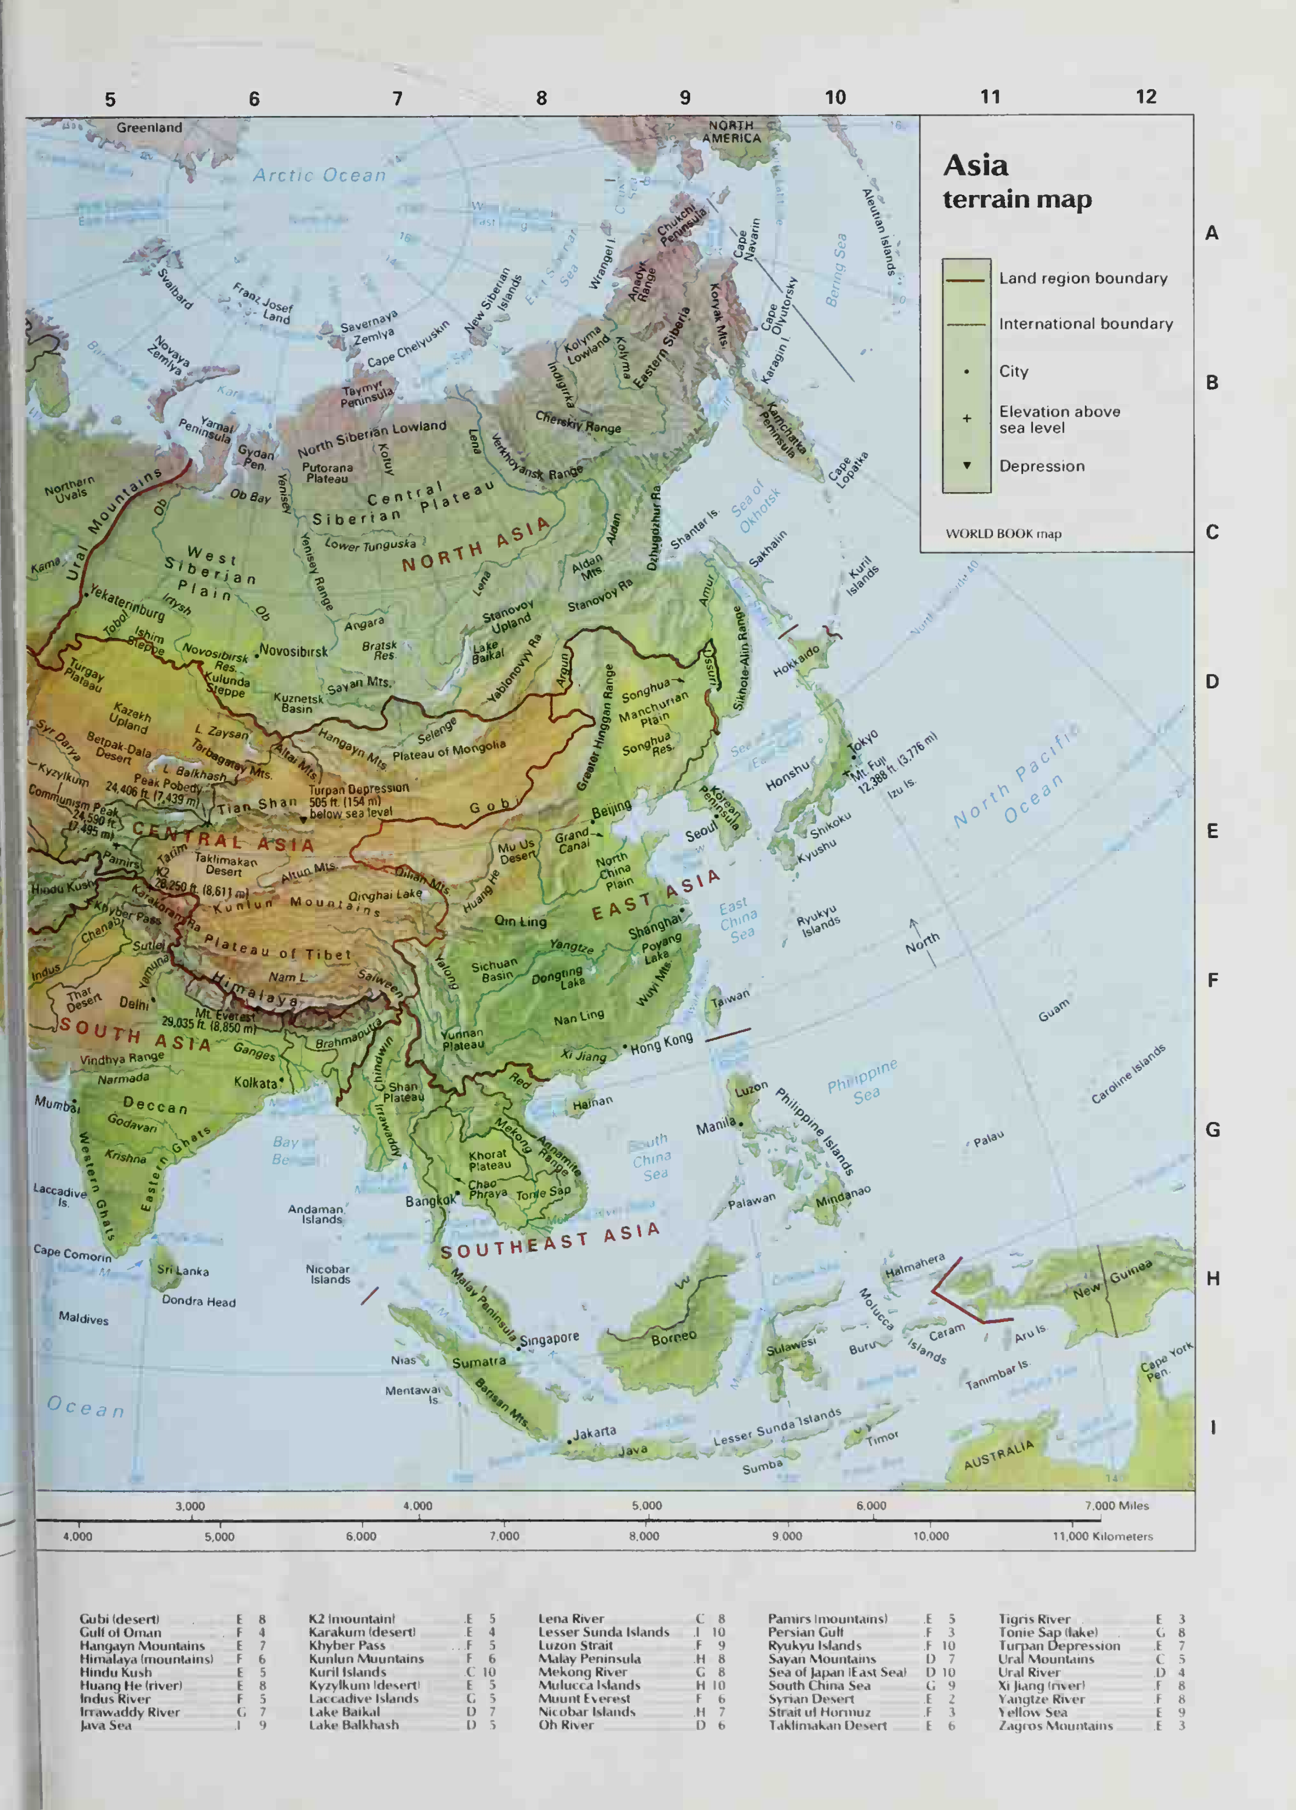
The Red Sea lies between the continents of Asia and Africa. The Aegean, Black, and Caspian seas make up part of the boundary between Asia and Europe. The Caspian Sea, which lies north of Iran, is the world's largest inland body of water. It is not really a sea but a salt lake that covers 143,250 square miles (371,000 square kilometers).



Other lakes include Lake Baikal in Russia; Lake Balkhash in Kazakhstan; the Aral Sea, between Kazakhstan and Uzbekistan; and the Dead Sea, between Israel and Jordan. The Dead Sea shore, about 1,310 feet (399 meters) below sea level, is the lowest place on earth.

Climate

Because of Asia's tremendous size, its regions have a wide variety of climates. These varied climates include the bitter cold of the polar north; the hot, dry desert environment of Central Asia and Southwest Asia; and the hot, humid conditions of the tropical south. The large map in this section illustrates Asia's climate patterns. The smaller maps provide statistical information on temperatures and precipitation.



Winds called *monsoons* influence the climate of much of Asia. A monsoon blows regularly in the same direction during definite seasons. In winter, monsoons from the north move into East Asia and cause cold, dry weather. The wind switches in summer and blows from the seas that lie south and southeast of that region. It causes hot, humid weather.

Most of East Asia's rain falls between April and October. The rainfall is heaviest in the east, and it decreases away from the sea.

Monsoons pass through South Asia and Southeast Asia from November to March. They cause the coolest weather in those two regions. Beginning in April, monsoons from the southwest send temperatures soaring. From May to October, wet monsoons bring heavy rains from the south seas. Many of these monsoons cause floods.

In Southwest Asia, monsoons affect only the southern and southwestern coasts of the Arabian Peninsula. Most of Southwest Asia has long, hot summers and mild winters. Inland, temperatures often climb above 115 °F (46 °C) in summer. But there are no clouds to keep the daytime heat close to the earth at night. A warm but comfortable night may follow an extremely hot day. The

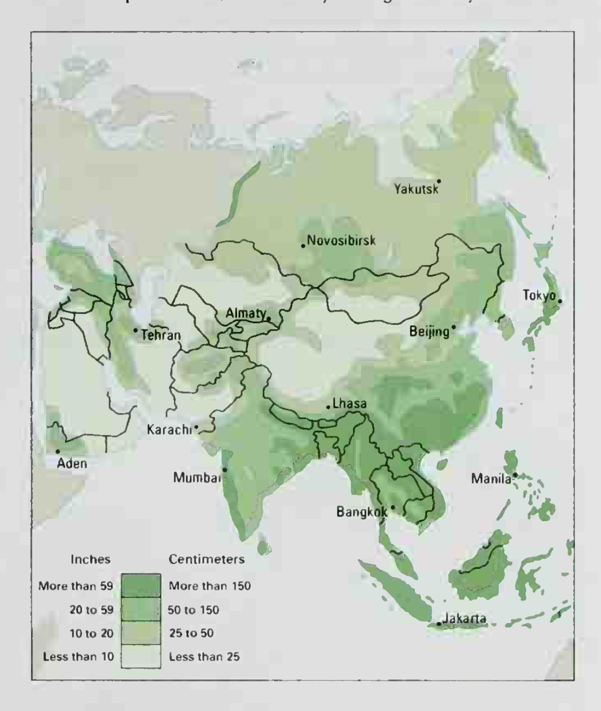
Climate regions in Asia

region's heaviest rains fall in Turkey near the Black Sea and in the Caucasus region between the Black and Caspian seas. Some parts of the Arabian Peninsula receive no rain for several years at a time.

Bitter cold polar weather keeps part of northern Siberia's land frozen the year around. In the grasslands in the southwest, the temperatures vary from 3 °F (−16 °C) in January to 64 °F (18 °C) in July. Central Asia's climate ranges from extremely cold in its mountain regions to extremely hot and dry in the deserts in the summer.

Animals

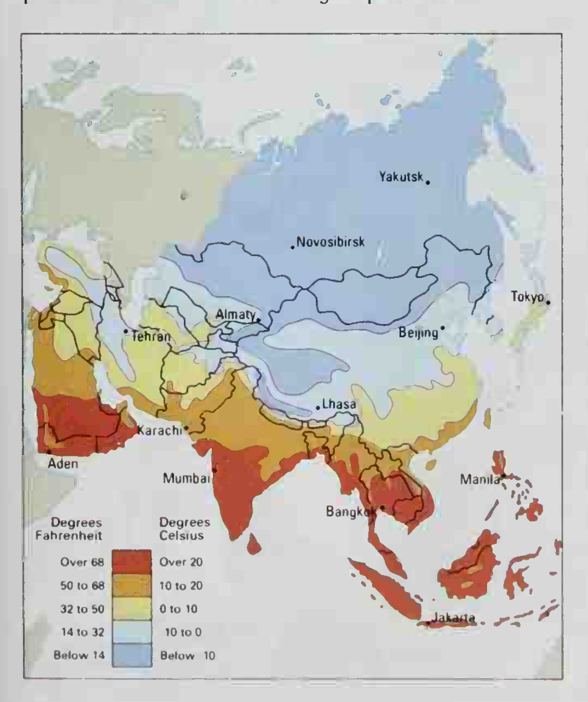
Domesticated animals. Many Asian people use *domesticated* (tamed) animals to do work and as sources of food, clothing, and shelter. Domesticated animals include the dromedary and other camels of Southwest Asia and the elephant and ox of South Asia. Other domesticated animals used by Asian people are the yak and Bactrian camel of Central Asia, the water buffalo of Southeast and East Asia, and the reindeer of North Asia.



Wild animals. Arctic foxes, Arctic hares, lemmings, and reindeer live in the Arctic. The lemmings live under the snow in the winter. Many animals in North Asia south of the Arctic are highly valued for their fur. They include brown bears, elks, ermines, lynxes, martens, otters, and sables.

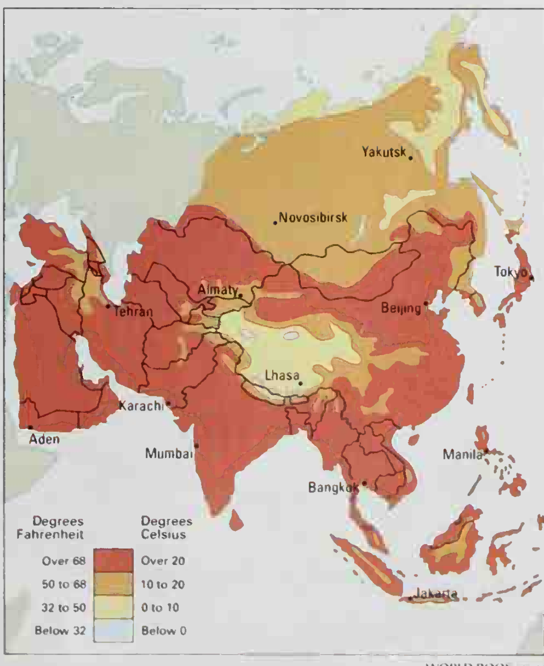
Antelopes, burrowing rodents, and locusts live in Mongolia and northwestern China. From time to time, swarms of locusts attack the fields of northern China, eating the crops in their paths. The giant panda, a black-

Average yearly precipitation



(Rain, melted snow, and other moisture)

Most of the rainfall in Asia is caused by the summer monsoon (a warm and moist southerly wind). The monsoon does not reach the central part of Asia, which is dry throughout the year.



Average January temperatures

This map shows the average January temperatures in Asia. The Himalaya forms a barrier against the cold northerly winds and protects southern Asia from freezing temperatures.

Average July temperatures

This map shows the average July temperatures in Asia. Most of the continent is hot, with the exception of northern Siberia and the high plateaus and mountain ranges of Central Asia.

WORLD BOOK maps

and-white bearlike animal, lives in the wild only in China. Much of East Asia is so crowded with people that few wild animals live in the region.

South and Southeast Asia have the continent's greatest variety of wild animals. Apes and monkeys and beautiful tropical birds are plentiful in these regions. Some animals—including crocodiles, leopards, rhinoceroses, scorpions, tigers, and poisonous snakes—endanger the rural people.

Wild animals of Southwest Asia include antelopes, caracals, onagers, and ibexes and other wild goats. The region's deserts support many insects and reptiles.

Plants

Few kinds of plants can survive in the Arctic area of North Asia. But the world's largest fir and pine forest lies south of the Arctic. Its trees supply lumber, pulpwood, and other products.

The dry land of most of Central Asia supports little plant life except for grasses. But grass serves as the food for livestock, the basis of Central Asia's economy.

Valuable plant life grows in eastern East Asia, which has plentiful rain. Trees supply East Asians with fruit, lumber, and paper. The people use one fruit tree, the mulberry, in an unusual way. They feed its leaves to silkworms, which produce silk thread for clothing.

Much valuable plant life also grows in the warm, wet climate of Southeast Asia and parts of South Asia. Products from plants account for a large part of the exports of these regions. People in many parts of the world use products from the nutmeg, rubber, and teak trees, the tea bush, and bamboo grass.

Animals of Asia This map provides a general idea of where some animals of Asia live. Most of the animals shown are wild. People have trained others, including camels, reindeer, and water buffaloes, to do work.

WORLD BOOK map
WORLD BOOK illustrations by Guy

Few plants grow in much of the dry parts of Southwest Asia. But date palms and olive trees of desert oases provide important parts of Southwest Asian diets. Dates and olives are also sold for export.

The opium poppy is grown in parts of Asia, including Afghanistan and Myanmar. Such powerful drugs as heroin, morphine, and opium are made from this flower. Doctors prescribe such drugs to ease pain and for other purposes. But some people use these drugs just to "get high." The drugs are addictive, and many users become drug addicts and ruin their physical and mental health (see **Drug abuse** [Abuse of illegal drugs]).

Agriculture

Agriculture is by far the most important economic activity in Asia. About three-fifths of the people make a living from farming. Farm products also account for the majority of Asia's exports.

In many Asian countries, most of the farmers use hand tools, and many have animals that pull plows and do other work. Yet in such countries as China and Bangladesh, intensive hand labor by farm families plus using every bit of available land produces high crop yields. But these nations have so many people that there is barely enough food to go around.

The use of modern farm tools and chemical fertilizers has become widespread in some Asian nations, including Israel, Japan, and the countries that were formerly part of the Soviet Union. Some Asian nations have increased farm productivity by the use of irrigation and new, higher-yielding rice and wheat seeds. These countries include China, India, South Korea, and Thailand.

Plants of Asia This map provides a general idea of where some plants of Asia grow. Little plant life grows in the cold of the Far North. Warm and wet South and Southeast Asia have a wide variety of plant life.

How the land of Asia is used

This map shows the different uses of land in Asia. The most important crops—such as wheat in Russia, rice in southern China, and rubber in Southeast Asia—are shown in larger type. Large areas of Asian land are generally unproductive because they are either extremely cold or too dry and not irrigated.

Generally unproductive land

This section gives an overview of how farms are organized in Asia and of Asia's major crops and livestock animals. The six *Way of life* sections of this article provide more information on how rural Asians live and work.

Farm organization in Asia follows three chief systems: *private ownership, tenant farming,* and *collective farming.*

Some farmers in all parts of Asia own their own farms. Private farm ownership is most common, however, in South Asia and on the mainland of Southeast Asia. Many farmers in these areas own a small plot of land.

Tenant farming is also practiced in many parts of the continent but is probably most common in Southwest Asia. Many farmers in that region work on land they rent from wealthy landlords. They pay the landlords with crops or money.

Few collective farms still exist. Israel has many collective farming communities called *kibbutzim,* and there are still some collective farms in China.

The Communist countries of Asia formerly practiced collective farming, but it proved inefficient and unpopu-

lar. The Chinese government introduced collective farming communities called *communes* in 1958 but began abandoning them in 1979. The government then tried a system similar to tenant farming. Farm families produced a certain amount of crops for the state. They could sell whatever excess they produced on the open market. The Chinese government gradually relaxed its crop requirements. Now many farm families raise and sell crops as they choose.

Crops. South Asia, Southeast Asia, East Asia, and southwestern North Asia rank as the continent's main crop-growing regions. The land and climate of most of Southwest Asia, Central Asia, and North Asia are poorly suited to farming.

The chief crops of Asia are rice and wheat. The countries of Asia—led by China and India—produce more than 90 percent of the world's supply of rice. Asia's leading wheat-producing countries include China, India, Russia, and Turkey.

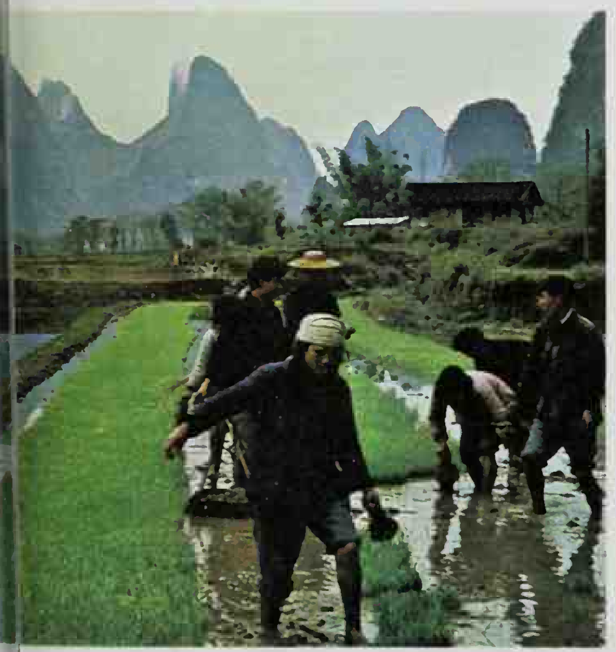
Most of the world's natural rubber and tea come from Asia. Indonesia, Malaysia, and Thailand are the top natural-rubber producers in the world. Asia's leading tea-growing countries include India, China, Sri Lanka, and Indonesia.

Other important Asian crops include cotton, *jute* (fiber from which burlap is made), and sugar cane. China, India, Pakistan, Turkey, Turkmenistan, and Uzbekistan stand among the leading cotton-growing nations. Jute comes chiefly from Bangladesh, China, and India. India ranks second in the world in the production of sugar cane. Only Brazil produces more.

Livestock. In South Asia, farmers who raise livestock use the animals chiefly to help with the work. In the less fertile parts of Central, North, and Southwest Asia, many people raise livestock for a living. They get cheese, milk, and meat from their animals, as well as fur and hides for clothing and shelter. Manure from livestock is used as fertilizer and sometimes as a cooking fuel.

Some of the animals are used for transportation. Livestock farmers also sell animals or products made from them to buy supplies.

Hogs and poultry are raised for food throughout most of East Asia and Southeast Asia. Camels, goats, and sheep are the most important livestock in Southwest Asia. Central Asians herd Bactrian camels, cattle, goats, horses, pigs, sheep, and yaks. Reindeer herding is a major activity in the northern part of North Asia.



Industry

Industry is growing rapidly in many East and Southeast Asian nations. These countries have prospered as their industries have expanded. But most other Asian nations have relatively little manufacturing and depend heavily on agriculture.

Mining. Raw mined materials rank among Asia's most important exports. Southwest Asia supplies a large part of the world's oil. Southeast Asia provides much of the world's tin. China exports large amounts of antimony and tungsten. Manganese and mica from China and India and chromite mined in Turkey and the Philippines are exported to many parts of the world.

Asia exports most of its raw mined materials to industrialized nations on other continents. Asia's factories cannot use all of the continent's mined products.

Manufacturing. During colonial days, Asia served as a source of food for Europe's people and as a source of raw materials for its industries. The processing of food and other products became important in Asia, and it

Marc Riboud, Magnum

A. L. Goldman, Rapho Guillumette

Agriculture provides a living for more than half of all Asians. Most Asian farmers, like the Chinese rice growers shown wading in water, perform many tasks by hand. A growing percentage of the farmers, including the Israeli beet growers shown riding a tractor, use modern farm machinery.

Heavy manufacturing takes place chiefly in technologically advanced countries such as China, India, Japan, Russia, South Korea, and Taiwan. The factory shown here is in China. Many Asian nations, however, have relatively little manufacturing.

Bernard Wolf, DPI

The handicrafts industry provides work for many Asians. Women in Sri Lanka, *shown here*, make beautiful designs on textiles. People throughout the world buy Asian handicrafts.

still is today. Such industries as sugar refining and the processing of fish, rice, and tobacco have major economic importance in some parts of the continent.

Most of Asia's heavy manufacturing takes place in such countries as China, India, Japan, Russia, South Korea, and Taiwan, all of which have large, modern factories. Industries in these countries make such products as automobiles, electronic equipment, factory machinery, iron and steel, military weapons, and ships. Israel, North Korea, Singapore, and Turkey also have some heavy industry.

Other industries. Light industries play an important role in the economies of such countries as Indonesia, Malaysia, and Thailand. Many Southeast Asian countries manufacture textiles, footwear, personal electronic products, and other consumer goods.

Millions of Asians who live along the seacoasts and rivers catch fish for a living. China, India, Indonesia, Japan, Russia, and Thailand rank among the most important fishing nations of the world.

Tourism and a related industry, handicrafts, have great economic importance in many parts of Asia. Large numbers of non-Asians visit the continent each year, and many Asians travel outside their home countries within Asia. The tourists spend money on food, transportation, and shelter.

Tourists also buy handicrafts made by Asians. The handicrafts include carvings, leather goods, metalware, pottery, rugs, and textiles. The tourist industry is especially active in South, Southeast, and East Asia.

Industrial development. Many Asian governments are trying to improve the economies of their nations by creating new industries and by expanding old ones. They have taken various steps toward industrialization. Some countries offer low tax rates to non-Asian business people to set up businesses in Asia. Asian governments have also used their own funds and aid from other countries to establish industries. The governments sold some of these industries to Asian businesspeople at low cost. Many changes in Asian education are aimed at training people in industrial skills.

The governments of Asia's Communist countries have attempted to increase industry by tight government control and by economic planning. In the late 1900's, however, both China and Vietnam began to loosen government controls and to encourage private enterprise.

A number of Asian countries have succeeded in increasing their industry. Japan is one of the world's leading industrial nations. It exports cars, electronics, and other consumer goods throughout the world. Israel, South Korea, and Taiwan have also made great progress in industrial development.

Other Asian countries have made some industrial progress, but they continue to be less developed compared to most industrial nations. China and India have huge factories and manufacture a wide variety of goods. But they still must import many items, and most of their people have a low standard of living. Such other Asian nations as Malaysia, Pakistan, the Philippines, Thailand, and Turkey are developing modern industry. Saudi Arabia and other oil-producing nations have large oil refineries.

Most other Asian countries have little industry other than the processing of agricultural products and raw

materials. The Asian countries that were formerly part of the Soviet Union face the need to replace their old industrial equipment and to develop new markets for their goods.

Transportation and communication

The transportation and communication systems of Asia's cities are more advanced than those of the rural areas. The cities have many of the same modern devices that Western cities have. But in some rural areas, transportation and communication differs little from that of hundreds of years ago.

Transportation. Many kinds of vehicles transport people and goods in Asian cities. Automobiles, buses, motor scooters, and trucks speed by vehicles powered by people or animals. People supply the power for such vehicles as bicycles and pedicabs. The pedicab, a taxicab operated like a bicycle, has largely replaced the jinrikisha and other taxis pulled by runners (see Jinrikisha; Pedicab). Oxen, water buffaloes, and other animals pull carts through the streets of some cities.

Motor vehicles are less common in rural Asia. Buses travel along the rural roads, many of which are unpaved. Some people share the ownership of a jeep. Many vil-

Mining and manufacturing in Asia

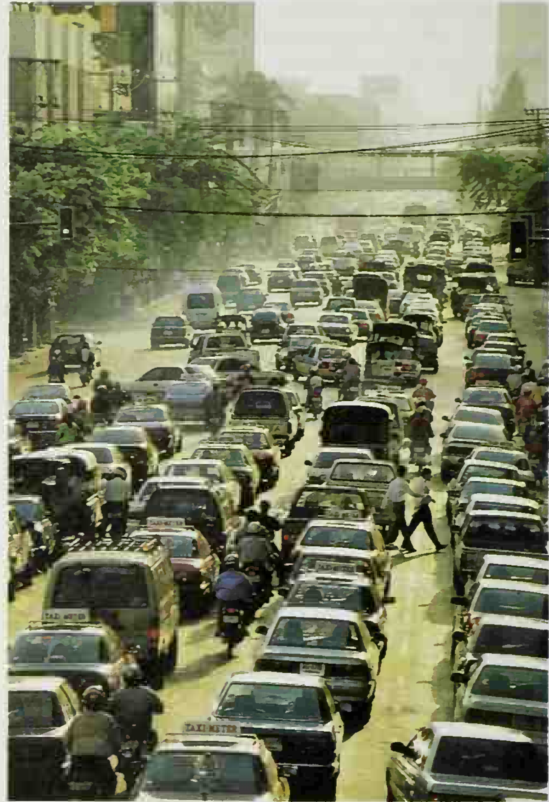
WORLD BOOK map

lagers transport goods in carts pulled by animals or people. Others travel by foot—to save wear and tear on their animals. Carts get stuck in the soft sands of the deserts, so many people use the sure-footed camel for desert transportation.

Rivers rank among the chief transportation routes of rural Asia. The people use barges, canoelike vessels, junks, sampans, and other small boats for travel and to transport goods. Junks and some other boats of rural Asia have sails and are moved by the wind. But many Asians must paddle their boats or move them by pushing a long pole against the river bottom. Sometimes, people on shore pull heavy barges by means of long ropes attached to the barges. People in Iraq sail an unusual boat called a *kufa* that looks like a huge bowl.



Airlines link most large Asian cities with one another and with other parts of the world. But railroads are still the continent's chief means of long-distance transportation. Colonial rulers built a large network of railroads during the late 1800's. They used trains to carry raw materials from inland areas to coastal cities and ports. Today, almost all Asian countries have at least one railroad. More trains are needed, however, to handle increased passenger and cargo loads. Asia also has a shortage of railroad managers, train repair personnel, and replacement parts for old trains. Japan, with one of the world's most modern railroad systems, is a major exception.

The colonial rulers also built up Asia's highway system between inland areas and coastal cities. Since the end of colonial rule, Asian nations have continued to build or improve highways so that more trucks and buses can use them.

Oceangoing vessels carry much cargo to and from Asia's ports. These huge, modern ships tower above the small, old-fashioned sampans and other boats that dockworkers use while loading and unloading them.

Communication in some Asian countries is much the same as in Western countries. Many people read newspapers. Radio and television stations broadcast from most cities. Most households have radios, and many own television sets. In Oman, for example, about 7 out of 10 people own a television set.

In other Asian countries, newspapers, radio stations, and TV stations are less numerous. Broadcasts do not reach some rural areas. Some families own radios, but few own television sets. In Myanmar, for instance, only about 1 person out of 200 owns a TV set. Satellite television receivers and mobile telephones enable some rural communities to stay in touch with the rest of the world, however.

Motor vehicle transportation has become common throughout much of Asia. These residents of Bangkok, Thailand, face thoroughfares crowded with traffic.

Van Bucher, Photo Researchers

Railroads, a leading means of long-distance transportation in Asia, carry cargo and passengers. This Indian commuter train is so crowded that riders hang out of the doorways.

History

Four areas of the world are sometimes called the *cradles of civilization* because of the important early civilizations that began there. One of these areas is in Egypt, and the other three are in Asia. The Asian cradles of civilization are (1) the Tigris-Euphrates Valley, now mostly Iraq; (2) the Indus Valley of South Asia; and (3) the Huang He and Yangtze valleys of China, in East Asia.

The Tigris-Euphrates Valley, near the head of the Persian Gulf, was the site of the world's first civilization. This valley forms the center of a larger historic region called the Fertile Crescent. This region, named for its rich farmland, follows the Tigris and Euphrates rivers north and west from the Persian Gulf. Then it curves south through the valley of the Jordan River. The region includes parts of what are now Iraq, Israel, Jordan, Lebanon, and Syria.

Ruins of old cities dot the Fertile Crescent. Archaeologists have discovered much about the ancient civilizations that existed in the area between about 3500 B.C.

and the 200's B.C. These civilizations included the Sumerian, Babylonian, and Assyrian civilizations.

The Sumerians developed the world's first civilization about 3500 B.C. They invented a method of writing, called *cuneiform,* and used it to inscribe clay tablets. The Sumerians traded widely with other peoples, including the Egyptians. Sumerian armies had war chariots a thousand years before the Egyptians did. The Sumerians also developed a complicated system of laws governing weights, measures, and trading.

No one really knows why Sumer declined. But by about 1900 B.C., the first of several great Babylonian dynasties appeared in the region north of Sumer. Babylon became the capital city of an advanced civilization that gained fame for its laws, religion, and walled cities.

The Assyrian Empire, north of Babylonia, began to expand after 883 B.C. For about 100 years, from 728 B.C. to 626 B.C., Assyria controlled Babylonia. Babylonia regained its independence after King Ashurbanipal of Assyria died in 627 B.C. But the Persians conquered the empire in 539 B.C.

The Persian Empire reached its height about 520 B.C. At that time, it included much of Southwest Asia and parts of South Asia, the southern part of Russia, and North Africa. Persia's importance lasted nearly 200 years. Alexander the Great conquered the Persian Empire in 331 B.C.

The Indus Valley. From about 2500 B.C. to about 1700 B.C., an advanced Bronze Age culture developed in South Asia. This civilization spread through the valley of the Indus River and included hundreds of settlements in what are now Pakistan and northwestern India. Scholars do not know how the Indus society began, nor if its people were related to the peoples of Southwest Asia.

About 1500 B.C., nomadic tribes called Aryans invaded India. The Aryans probably came from the plains north of the Caspian Sea. They gradually spread their culture eastward to the Ganges Valley. The Aryans developed the religious and social practices that formed the basis of later Hindu cultures. By 517 B.C., the Persian Empire had started to overrun the Indus Valley.

From 327 to 325 B.C., Alexander the Great conquered the Indus area. But he soon gave up his rule over the area, and India came under the control of Buddhist rulers. Buddhist dynasties controlled much of the Indian subcontinent for hundreds of years. The greatest empire in this period was that of Ashoka. He united nearly two-thirds of South Asia during his rule, which lasted from about 272 B.C. to 232 B.C. Art and literature thrived during Ashoka's reign.

The Huang He and Yangtze valleys of north and central China make up the third early center of Asian culture. In the Huang He Valley, during the 1700's B.C., the Shang dynasty became the first major civilization of East Asia. Palaces filled the Shang capital of Anyang. Shang priests used *pictographs* (simple drawings representing words) to report events and keep records. This early picture writing formed the basis of the written Chinese language.

The Zhou (also spelled Chou) dynasty replaced Shang rule about 1122 B.C. The Zhou dynasty was centered in the Yangtze Valley. During Zhou rule, Chinese art and learning flourished. Great thinkers, such as Confucius and Laozi (also spelled Lao Tzu), laid the basis of East Asian philosophy. Feudal wars weakened the Zhou dynasty after 403 B.C., and the dynasty ended in 256 B.C. Several large states controlled China until 221 B.C., when the Qin (also spelled Ch'in) dynasty took over.

Qin rulers created the first united Chinese empire. The first Qin ruler, Shi Huangdi, ordered major construction on the Great Wall of China in an attempt to protect the empire from the nomadic peoples of the north. But rebel warriors overthrew the Qin rulers in the late 200's B.C. China's next dynasty, the Han, ruled a large empire from 202 B.C. to A.D. 220.

Nomadic invasions destroyed ancient civilizations in all parts of Asia after A.D. 300. For centuries, nomadic barbarians poured out of Central Asia and southern North Asia. In East Asia, during the 300's, the Huns of Mongolia conquered northern China. Then they turned west and invaded Europe, where they contributed to the fall of the Roman Empire. In about 500, Huns ended India's 180-year-old Gupta Empire.

East Asia had peace from the early 600's to the 1100's, when nomadic invasions and religious wars weakened western Asia. The Tang and Song (also spelled Sung) dy-

Asian civilizations and empires of ancient times

These maps show the locations of some of the most important civilizations and empires of Asia during ancient times. The map at the left locates the Asian *cradles of civilization*—areas where important early civilizations developed. The other maps show the extent of some of the major early empires in Asia.

Cradles of civilization

300's and 200's B.C.

Shi Huangdi's tomb is surrounded by an army of life-sized terra cotta statues of soldiers. In the 200's B.C., Shi Huangdi united China for the first time and began the famous Great Wall of China.

nasties ruled China during that period. They developed gunpowder, printing, paper money, and porcelain.

Muslim peoples conquered Southwest Asia during the 600's and built an empire that included North Africa and most of Spain and Portugal. From the 300's to the 1100's, the Byzantine Empire in the eastern Mediterranean area was the only Christian power in Asia. That Christian influence eroded as the empire fell to the Ottomans, a Muslim people from Central Asia. Over several centuries, the Ottomans steadily occupied Byzantine territories and established a great Muslim empire called the Ottoman Empire. In 1453, they captured the Byzantine capital, Constantinople, which then became known as Istanbul.

New barbarian invasions came from the center of Asia after 1206 when Genghis Khan united Mongol tribes and conquered northern China, northern India, Persia (now Iran), and parts of Europe. The Mongol Empire extended from China and Korea to the Danube River in Europe. It was the largest land empire in history. The empire lasted until 1368, but it achieved its greatest importance during the mid-1200's under Kublai Khan.

After the fall of the Mongol Empire, the Ming dynasty gained control of China and spread its power throughout most of East Asia. During the nearly 300 years of Ming rule, Chinese art and literature flourished.

In 1526, Mongols again invaded India and established the Mughal Empire. About the same time, the Ottoman Empire reached its height in Southwest Asia. Ottoman rule also extended to North Africa and southeastern Europe. But none of these empires remained powerful. Europeans had entered a period of cultural and economic expansion that resulted in their conquest of Asia.

The Western conquest of Asia began during the early 1500's. The desire for Asia's riches—especially control of the spice trade—excited all Europe. An age of colonial expansion followed. In the 1500's, the Portuguese took control of the Indian Ocean and, farther east, obtained Macao and Melaka as ports for trade. The Spanish began trading in the Philippines about 1565. The English and Dutch entered the Asian trade after 1600. The Dutch gained a foothold on Java in 1619. They took Melaka from the Portuguese in 1641 to control the spice trade.

In Japan, the strong Tokugawa rulers forced the Spanish and Portuguese to leave the country in 1639. Japan allowed only the Dutch to send a ship to trade at Nagasaki once a year. China, under the Qing dynasty of the Manchus, also closed its doors to the West. Foreign traders were permitted only at Guangzhou (Canton).

The British and Dutch, stopped from trading with China and Japan, turned to South and Southeast Asia. The British gradually conquered most of India, and the Dutch took over the East Indies (now Indonesia). At about the same time, European Russians pushed into Siberia from the west.

The age of colonialism. Europe and the United States brought their economic and military strength to bear on Asia during the 1800's. In 1839, China and the United Kingdom began the Opium War, a battle over opening China to imports. China lost and, in 1842, agreed to British trade at five Chinese ports. Two years later, China began trading with the United States and France. In 1854, Matthew C. Perry, the leader of an

Asian empires in medieval and modern times

These maps show the locations of some of the major empires in Asia from the A.D. 700's to the 1700's. The Mongol Empire, *center,* was the largest land empire in history. It extended all the way from China and Korea to the Danube River in Europe.

During the colonial period—the 1500's to the mid-1900's—Europeans controlled much of Asia. The Europeans used Asian natural resources to help their own nations' economies. Only a small percentage of Asia's people benefited economically from the colonial system. This picture shows British rulers and their Asian servants in India during the mid-1700's.

United Press Int.

Mohandas K. Gandhi, *center,* was an Asian leader in the struggle for independence. He led India's movement for independence from British rule.

American naval mission, signed a treaty that opened Japan to limited U.S. trade.

A period of fierce competition began among Western powers for Asian trade and colonial expansion. The United Kingdom became a powerful force in Southwest Asia, India, and southern China. Russia expanded into Central Asia and Manchuria. The French colonized Indochina. The United States acquired the Philippines from Spain in 1898, after the Spanish-American War.

By the 1900's, Western influence had produced great changes throughout Asia. Western art influenced Asian art, and the colonials built large parts of Asian cities along Western lines. The colonial powers played the leading part in the economic and political life of much of Asia.

The colonials made great profits through their control of Asia. At the same time, large numbers of Asians lived in poverty and had no voice in their government. Many Asians were dissatisfied with colonialism and demanded that Asians rule Asia. Feelings of nationalism grew up in many parts of the continent. In time, these nationalist movements ended colonialism in Asia.

The rise of the Japanese Empire. Japan overthrew the Tokugawa system of government in 1867. After adopting a constitutional monarchy in 1889, Japan quickly rose to great power in eastern Asia. From 1894 to 1905, in wars with China and Russia, Japan won the island of Taiwan and a foothold in Manchuria and Korea.

A new Chinese republic replaced the Manchu dynasty in 1912. But China found it difficult to build a strong new government. For many years, war lords fought for control of the country. Finally, in 1928, the Chinese Nationalists united China under one government. But the Nationalists still had to contend with rival Communist groups, which left the nation open to attack.

In 1931, Japanese troops invaded Manchuria. Six years later, they swept into central China. The troops left China only partly conquered and began to drive toward Southeast Asia and the Pacific Islands.

In 1941, Japan joined Germany and Italy in World War II. At the height of its power, in 1942, the Japanese Empire extended from the Aleutian Islands of Alaska, south to the Netherlands Indies, and as far west as Burma (now Myanmar). The huge empire collapsed with Japan's defeat in 1945. See **World War II** (The war in Asia and the Pacific).

The end of colonialism. The Allied victory in World War II returned most of the colonies to the Western powers, but only for a short time. Feelings of nationalism in Asia had grown during the war. Mohandas K. Gandhi, who led India's movement for independence from the United Kingdom, was perhaps the most famous Asian nationalist.

Between 1943 and 1949, Burma (now called Myanmar), Ceylon (now called Sri Lanka), India, Indonesia, Pakistan, and the Philippines changed from colonies into nations. A number of Southwest Asian colonies and territories also became independent nations. In addition, a new nation, Israel, was formed in 1948 as a homeland for Jews. In 1949, Indochina was the only part of Asia that still had major Western colonies. However, that region was torn by revolt and gained independence five years later.

Results of colonialism. With the end of colonialism, Asian nations again controlled their own development. But years of colonial rule had left Asia poorly prepared in some ways to face the modern world.

Economically, Asia lagged far behind the West. An industrial boom in the West, which began during the 1700's, provided jobs for the rapidly increasing population. The boom enriched governments and business people and gradually raised the living standard of

most of the population. The West also made major improvements in farm tools and methods.

Under colonial rule, Asia had provided raw materials needed for Western industry. But most of Asia did not become industrialized. Nor did the continent experience much agricultural improvement. As a result, poverty became more widespread in Asia than in the West by the end of the colonial period.

Colonialism also slowed Asia's political and military development. At the same time Western nations ruled Asia, they developed a tradition of strong central government that their colonial possessions lacked. After the Europeans left, various groups in many Asian nations struggled for political power. In many cases, Asians who came to power had difficulty establishing their authority over all the people in their countries. Political factions divided many nations.

Western nations developed militarily as well as industrially and politically during the colonial period. But in Asia, the colonial rulers—not the Asians—were responsible for the military defense of the lands they governed. After the colonial rulers left, many Asian nations found themselves without suitable military protection. This military weakness added to Asia's problems.

Foreign influence in Asia—1914

This map shows Asia in 1914. Cities under colonial rule are shown by circles. Treaty ports, which handled international commerce, are shown by black dots. Pink stripes show the sphere of British influence, green stripes the Russian sphere.

The spread of Communism. Two Asian nations—the Soviet Union and Mongolia—turned Communist long before World War II. (The Soviet Union had been formed in 1922, under Russia's leadership.) By the time the war began in 1939, Communist parties had gained strength in many other parts of the continent. The Communists spoke out against colonial rule and used their stand against colonialism to gain followers. During World War II, many Communists fought alongside the Allies, some of which were colonial powers. But after the war, the Communists called for an end to colonialism and sought power for themselves.

In 1949, the Chinese Communists defeated the Chinese Nationalists. Mao Zedong led the Communists in their 22-year struggle for control of China. With this victory, Communists controlled Asia's two largest nations—China and the Soviet Union.

At the end of World War II, Korean Communists took control of North Korea, and non-Communist Koreans took South Korea. In 1950, the North Koreans invaded South Korea, touching off the first international war between Communists and non-Communists. The United States and other non-Communist nations fought on the side of the South Koreans. North Korea's allies included China, which sent troops, and the Soviet Union, which sent supplies. The Korean War ended in 1953. But Korea still remains divided between a Communist north and a non-Communist south.

Communism also gained a foothold in Southeast Asia. In 1946, Communists in Vietnam, which was then a colony of French Indochina, began a long war against the French forces there. A nationalist group called the Vietminh led the movement. It was headed by the Communist leader Ho Chi Minh. The Communists finally defeated the French in 1954. Indochina was then divided into four independent nations—Cambodia, Laos, North Vietnam, and South Vietnam.

The fighting did not end when the French left. Communists in Cambodia, Laos, and South Vietnam continued to fight the new non-Communist governments. North Vietnam sent troops and supplies to help them. China and the Soviet Union also sent supplies.

In the early 1960's, South Vietnam seemed about to fall to the Communists. The United States sent troops to help defend South Vietnam. A cease-fire agreement ended U.S. participation in the fighting in 1973. But clashes continued between the Vietnamese Communists and non-Communists. Battles also flared up in Cambodia and Laos during the 1960's and early 1970's. In 1975, Communists took control of South Vietnam, Cambodia, and Laos. North and South Vietnam were reunited in 1976. See **Vietnam War**.

When the countries of Asia became independent

More than 30 Asian nations have become independent since World War II ended in 1945. This map shows when the various countries of Asia gained their independence. Yemen (Aden) and Yemen (Sana) merged into the country of Yemen in 1990.

WORLD BOOK map

Communist rebels also fought against the governments of several other Asian countries, including Myanmar, the Philippines, and Thailand. But none of these rebellions succeeded.

In 1978, leftist military leaders took over the government of Afghanistan. Many Afghans rebelled against the new government. At the end of 1979, the Soviet Union began sending troops to help the Afghan government crush the rebels, who were called *mujahideen*. However, the government forces and their Soviet allies were unable to defeat the rebels. The Soviet Union withdrew its troops in 1988 and 1989. The war in Afghanistan between the rebels and the government continued until 1992, when the rebels overthrew the government.

By the end of 1991, the Soviet Union had ceased to exist as a country. First, Communist rule ended there after conservative Communist officials failed in an attempt to overthrow Soviet leader Mikhail S. Gorbachev. After the failed coup, most of the Soviet republics declared their independence. In December 1991, Gorbachev resigned, and the Soviet Union was dissolved. The former Soviet republics became independent nations.

Other struggles. Fighting in Asia has not been limited to the struggle between Communists and non-Communists. Ethnic group friction, power struggles within nations, border disputes, and other causes have led to fighting among many Asian peoples.

Israel and the Arabs of Southwest Asia and North Africa have struggled since the founding of Israel in 1948. The Arabs claim the Israelis have no right to establish a Jewish state in what Arabs consider their land. Since 1948, the Arabs and the Israelis have fought four wars. In the late 1970's, relations between Israel and the Arab country of Egypt improved. In the early 1990's, relations improved between Israel and both Jordan and the Palestine Liberation Organization (PLO), an Arab group that represents Palestinians. But in the early 2000's, fighting between Israel and the Palestinians increased.

Conflicts have also erupted between various groups of Muslims in Southwest Asia. In the 1960's, rebels battled government forces in Iraq; Syria; and Yemen (Sanaa), now part of Yemen. Iran and Iraq fought a war against each other from 1980 to 1988. In Lebanon, fighting broke out between Muslims and Christians in the mid-1970's, and among various Muslim groups in the 1980's. A peace plan ended most of the fighting in Lebanon in 1991. In 1990, Iraq invaded Kuwait. Many Southwest Asian nations and Western nations joined forces to drive Iraqi troops out of Kuwait in 1991.

The Kurds are a Muslim people whose homeland extends across the mountainous border regions of several Southwest Asian nations. In the late 1900's, the Kurds often battled the governments of those countries for the right to establish their own government.

India and Pakistan have disputed control of Kashmir since the two countries were formed in the late 1940's. Fighting has erupted many times in the region. Now that both nations possess nuclear arms, the Kashmir conflict ranks as one of the world's most troubling.

Civil war broke out in Pakistan in 1971. The government, centered in West Pakistan, ordered troops to put down a rebellion in the east. But forces from India joined the East Pakistanis and succeeded in defeating West Pakistan in December 1971. East Pakistan then became the independent nation of Bangladesh.

Indonesia occupied East Timor in 1975, after Portugal ended its colonial rule there. Many East Timorese opposed Indonesian control, and the United Nations refused to recognize Indonesia's claim. East Timor finally became an independent country in 2002.

In many Asian nations, Muslim militants have fought to gain power. In the late 1970's, Muslim revolutionaries overthrew the shah of Iran and established a conservative Islamic government. Muslim rebels also have fought the governments of the Philippines and several other Asian nations. The Taliban, an Islamic group that gained control of most of Afghanistan by the mid-1990's, imposed a harsh interpretation of Islamic law on that coun-

Pix

Communists battled Nationalists in China for 22 years before finally gaining control of the country in 1949. The spread of Communism led to much fighting in Asia during the 1900's.

Wide World

War raged in Vietnam for almost 30 years as Vietnamese Communists struggled to control the country. Beginning in 1965, United States troops fought as allies of the non-Communists.

Important dates in Asia

c. 3500 B.C. Civilization began in Southwest Asia.
c. 2500 B.C. Civilization developed in South Asia.
1700's B.C. Civilization developed in East Asia.
c. 563 B.C. Buddha was born in what is now Nepal.
c. 551 B.C. Confucius was born in China.
Before 4 B.C. Jesus Christ was born in the town of Bethlehem in Southwest Asia.
A.D. 317 The Huns from Mongolia conquered northern China, starting a series of nomadic invasions of Asia.
c. 570 Muhammad was born in Arabia.
661-750 Arab civilization spread in Southwest Asia.
1200's The Mongols conquered much of Asia.
1500's European nations began conquests in Asia.
1526 The Mongols set up the Mughal Empire in India.
1639 Japan closed its doors to influences from Europe.
1842 After a war with the United Kingdom, China opened five ports to trade with Western nations.
1905 Japan defeated Russia and took control of Russian interests in Korea and Manchuria.
1912 The Chinese overthrew their emperor.
1931 Japan invaded and occupied Manchuria.
1937-1938 Japan invaded and occupied central China.
1941-1945 Japan fought the Allies in the Pacific area during World War II—and lost all its possessions.
1940's-1950's Most colonial Asian nations won independence.
1946-1954 Vietnamese Communists fought France for control of Vietnam and gained control of North Vietnam.
1948 Israel was established as a Jewish homeland. The Arabs and the Israelis fought the first of four wars.
1949 The Chinese Communists conquered mainland China.
1950-1953 The Korean War pitted Communists in the northern part of Korea against non-Communists in the south.
1957 The Vietnam War began as a Communist rebellion in South Vietnam.
1965 The United States began sending troops to Vietnam.
1975 The Communist North won the Vietnam War. Communists also took control of Cambodia and Laos.
1980-1988 Iran and Iraq engaged in a war.
1990-1991 Iraq invaded and occupied Kuwait. An international force led by the United States drove Iraq out of Kuwait.
1991 Most republics of the Soviet Union declared their independence. The Soviet Union was dissolved.
1997 Control of Hong Kong returned to China from the United Kingdom.
1999 Control of Macao returned to China from Portugal.
2000 The leaders of North and South Korea met for the first time since Korea was divided.
2001 The United States and its allies drove the ruling Taliban from power in Afghanistan.

try. The Taliban also supported al-Qa'ida, the organization the U.S. government accused of being behind the terrorist attacks in the United States on Sept. 11, 2001. Later that year, the United States helped Afghan forces drive the Taliban from power.

A new era. Asia still faces many problems. Millions of people in Asia are poor and illiterate. Disputes between peoples continue to threaten peace in many areas. Despite these problems, much of Asia entered a new era of development in the late 1900's.

Parts of East Asia and Southeast Asia have progressed rapidly. In the 1990's, some of these countries became known as "Asian tigers" because their economies were so strong. These economies are based largely on high-technology industries and businesses, such as computer manufacturing. In Southwest Asia, Israel developed a strong economy less than 20 years after its creation. Earnings from oil have greatly improved the economies of other Southwest Asian nations. Economic progress enables governments to build new schools and train new teachers in an effort to raise educational levels. Today, a larger percentage of Asians than ever before attend school for at least a few years.

But economic progress in Asia has been uneven. In some nations, including Cambodia and Laos, development has been slow. In other nations, including China,

The Petronas Towers, among the world's tallest buildings, rise above Kuala Lumpur, Malaysia. Many East and Southeast Asian cities showed rapid growth in the late 1900's and early 2000's.

India, and Pakistan, progress has been mixed. Some parts of these countries have taken significant steps forward. Other parts remain poor.

Fewer Asians suffer malnutrition today, but millions still do not have enough to eat. The development of new high-yielding varieties of rice and wheat has helped reduce hunger in parts of the continent.

Political instability continues to slow progress in some Asian nations, but signs of hope exist. In 2000, for example, leaders of the two Koreas met for the first time since Korea was divided. Graham P. Chapman, Richard Louis Edmonds, Abraham Marcus, and Jonathan Rigg

Asia Minor is a peninsula of western Asia between the Black Sea and the Mediterranean Sea. Some people call it Anatolia. The Aegean Sea separates Asia Minor from Greece on the west. On the east, the peninsula extends to the upper Euphrates River. *Asia Minor* is the geographical name for the region. Turkey occupies all the land on the peninsula.

Asia Minor was one of the first places in the world to become civilized. It may have been here that people first learned the use of iron over 3,500 years ago. Archaeologists have found evidence of an advanced society that lived in the south-central area before 6000 B.C. The Hittite kingdom developed on the peninsula in 1900 B.C., and the Aegean peoples settled there in about 1200 B.C. The civilization of classical Greece had its beginnings among the Ionian Greeks of Asia Minor. The Romans

Location of Asia Minor

took over the western part of Asia Minor in 133 B.C. They gained the rest of the peninsula around 50 B.C.

People from central Asia invaded Asia Minor in the A.D. 200's. Arabs attacked the cities of Asia Minor in the 600's, when the peninsula was part of the Byzantine Empire. The long period of Turkish control began in 1071. The Crusades and Mongol invasions of the 1200's and 1300's caused the breakup of the government set up by the Seljuk Turks and prepared the way for the rise of the Ottoman Empire. The area's resources were developed after the Turkish Republic was formed in 1923 (see Turkey [The Republic of Turkey]). F. Muge Gocek

Asia-Pacific Economic Cooperation (APEC) is a forum for the discussion of economic cooperation in the Pacific region. It consists of 21 nations and other political units that border the Pacific Ocean. APEC's aims include reducing trade barriers among its members and promoting trade and investment in the region.

Twelve nations have been members since the group was formed in 1989: Australia, Brunei, Canada, Indonesia, Japan, Malaysia, New Zealand, the Philippines, Singapore, South Korea, Thailand, and the United States. In 1991, China, Hong Kong, and Taiwan became members. Mexico and Papua New Guinea joined in 1993, and Chile in 1994. Hong Kong became a special administrative region of China in 1997 but kept its separate membership in APEC. Peru, Russia, and Vietnam became members in 1998.

In APEC's first two years, its members established 10 "working groups" to explore avenues for cooperation. Foreign and economic ministers of APEC countries have met annually since 1989. In 1993, APEC heads of state met for the first time. They established committees to seek regional cooperation in the areas of trade and investment, higher education, and human resource development. They also set up the Pacific Business Forum to promote closer cooperation with privately owned businesses. In 1994, they agreed to establish a free-trade zone among their countries by the year 2020. APEC has an administrative office in Singapore. Jeffrey J. Schott

Rudi Von Briel

Asian neighborhoods are part of many American cities.

Michael Newman, Photo Edit

A Vietnamese American family enjoy a meal together.

Asian Americans add their many different ethnic and cultural groups to the blend of American life. They make up the country's third largest minority group.

Asian Americans

Asian Americans are Americans of Asian descent. They or their ancestors came from Asian countries, particularly Cambodia, China, India, Indonesia, Japan, Korea, Laos, Pakistan, the Philippines, Thailand, and Vietnam. More than 10 million people of Asian descent live in the United States. They make up the country's third largest minority group, after Hispanic Americans and African Americans.

The first Asian immigrants who arrived in large numbers in the United States came from southeastern China. They immigrated to California in 1849, after gold was discovered there. In 1882, however, the U.S. government began placing restrictions on Asian immigration because of pressure from native-born Americans. Many Americans feared job competition from the newcomers and resented their "foreign" customs. It was not until 1965 that all restrictions against Asian immigration were lifted. Today, Asians are the country's second fastest growing minority group, after Hispanic Americans.

Who Asian Americans are

According to the 2000 U.S. census, about 3 $\frac{1}{2}$ percent of the United States population is of Asian descent. Asia, the world's largest continent, has 49 countries, so the Asian American population consists of many different ethnic and cultural groups. Chinese Americans form the largest Asian group, making up about 2 $\frac{2}{5}$ million of the 10 $\frac{1}{4}$ million Asian Americans. Filipino Americans are the second largest group, with about 1 $\frac{4}{5}$ million people. The next largest groups are Americans of Asian Indian, Vietnamese, Korean, and Japanese ancestry.

The contributor of this article is Hyung-chan Kim, Professor of Education and Asian American Studies at Western Washington University and editor of the Dictionary of Asian American History.

The languages of the many Asian American groups include Chinese, Hindi, Japanese, Javanese, Korean, Tagalog, Thai, and Vietnamese. Asian Americans practice several major religions, including Buddhism, Christianity, Confucianism, Hinduism, Islam, and Shintoism.

Asian American groups differ in physical appearance, language, and culture from one another as well as from other Americans. But Asian Americans have many of the same values most other Americans cherish. For example, most strongly believe in the importance of family. Many Asian Americans, particularly the most recent immigrants, uphold a family value called *xiao.* The Chinese character for the word combines the word *lao,* meaning old age or old man, with *zi,* which means son. In practicing xiao, the young honor the old, and the old respect and protect the young.

Success through hard work and self-discipline is another value emphasized in most Asian American families. Children are encouraged to work hard in and out of school to be worthy of the sacrifices their parents make for them. Self-control is also an important value. Children are taught that mature people do not show their feelings too readily.

Where Asian Americans live

Most Asian Americans live in the Western United States. According to the 2000 census, only about 22 percent of the total U.S. population lives in the West, but nearly half of the Asian population resides there. Almost 4 out of 10 Asian Americans live in California.

More than 95 percent of Asian Americans live in urban areas. About half of them have homes in cities, and about half live in suburbs. In cities, Asian Americans are often concentrated in their ethnic neighborhoods, which are usually known by such names as Chinatown or Little Tokyo.

Asian American accomplishments

Asians have been in the United States for only about 150 years. In spite of their short history, they have influ-

enced many areas of American culture. Asian Americans also have distinguished themselves in many fields.

Asian influences on American culture are reflected in many areas of life. *T'ai chi ch'uan* is a form of exercise that the Chinese have practiced for centuries. It has become especially popular among older Americans, who find that its slow, gentle movements provide good exercise for aging bodies. *Tae kwon do* is a traditional Korean *martial art* (fighting art). It has been popularized by Korean immigrants who teach it to American youth. *Judo* is a traditional Japanese form of wrestling. Many U.S. colleges offer it in physical education programs.

Chow mein and other Chinese foods are familiar to most Americans. Chow mein consists of steamed vegetables topped with chicken, beef, or seafood and served with fried noodles. A favorite for some Americans is *sushi,* a Japanese dish of vinegar-flavored rice and raw fish or vegetables. Restaurants that serve spicy Thai or Indian food are popular. Many U.S. groceries carry the Korean dish *kimchi,* a highly seasoned mix of Chinese cabbage, white radishes, and other vegetables.

Acupuncture is an ancient Chinese method of relieving pain and treating disease by inserting needles in the body. It has become accepted by the American medical profession as a way to treat certain ailments.

Individual achievements. Nuclear physicist Samuel Chao Chung Ting is among several Asian American winners of the Nobel Prize. He shared the 1976 Nobel Prize for physics for helping to discover a subatomic particle known as the *psi particle.* Subrahmanyan Chandrasekhar, an Indian-born astrophysicist, shared the 1983 Nobel Prize for physics for his contributions to the theory of invisible astronomical objects called *black holes.*

Award-winning Asian American athletes include Sammy Lee and Kristi Yamaguchi. Lee was the first nonwhite American to win an Olympic gold medal in high diving. He received the medal in 1948 and again in 1952. In 1992, Yamaguchi became the first Asian American to win an Olympic gold medal in figure skating. In 1997, Tiger Woods, at the age of 21, became the youngest golfer ever to win the Masters Tournament. Woods is partly of Asian American descent.

The first Asian American to serve in the U.S. Congress was Dalip Singh Saund. In 1956, he won election to the House of Representatives as a Democrat from California. He served from 1957 to 1963. Hiram L. Fong became the first Asian American to win a seat in the Senate. He represented Hawaii from 1959 to 1977. Daniel K. Inouye of Hawaii became the first Asian American to serve in both the House and Senate. He served in the House from 1959 to 1963, and has served in the Senate since 1963. The first Asian American woman in Congress was Patsy T. Mink of Hawaii. She first served in the House from 1965 to 1979. She again won election to the House in 1990 and has served there since 1991. George R. Ariyoshi became the first Asian American governor of a U.S. state. He was governor of Hawaii from 1974 to 1986.

Ellison S. Onizuka was the first American astronaut of Asian descent. Onizuka and his fellow crew members died in January 1986 when their space shuttle Challenger was destroyed in an accident just after launch.

A number of other Asian Americans have achieved success in their chosen professions. They include architects I. M. Pei and Minoru Yamasaki; authors Maxine

Ancient Chinese exercises called *t'ai chi ch'uan* are performed by large numbers of people throughout the United States. Many people practice t'ai chi outdoors early in the morning.

Where Asian Americans live

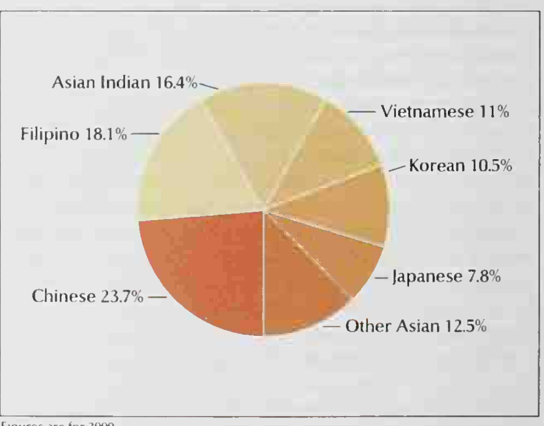
This map shows the state-by-state distribution of the U.S. Asian population according to the 2000 census. The numbers on the map indicate the percentage of Asians in the total population of each state.

WORLD BOOK map

Hong Kingston and Amy Tan; broadcast journalist Connie Chung; composer and video artist Nam June Paik; and orchestra conductors Zubin Mehta and Seiji Ozawa.

History of Asian immigration

Asian immigration to the United States did not begin until the mid-1800's, more than 200 years after the first wave of European immigration. One reason for the slower start is that the rulers of many Asian countries prohibited their subjects from going abroad. In some cases, people who were caught attempting to leave were put to death.



Another reason that Asians did not leave their homelands was that their societies were relatively stable. Asia did not experience the revolutions that brought political, economic, and social changes to Europe. The people had little reason to leave in search of a better life. But by the mid-1800's, the traditional Asian systems began to prove ineffective in the face of increasing social problems.

The first major social crises erupted in China. The government began to weaken under repeated foreign invasions, domestic revolts, and problems caused by overpopulation. The rulers could no longer control people who wanted to leave the country.

The first wave of Asian immigration. The news in 1848 that gold had been discovered on John Sutter's California property attracted many people to the state. In 1849, about 700 Chinese arrived hoping to find work mining gold. They were poor peasants from southeastern China. Most of them had not even been able to pay their fare to the United States. They received loans from merchants in their own country and made promises to pay off their debts after they found work in America. By the end of 1850, there were 4,000 Chinese in California. By 1860, the United States had a Chinese population of about 35,000, most of whom lived in California. Many newcomers who could not find work in the California mines obtained jobs building railroads.

California civic leaders and industrialists greeted the first arrivals of Chinese laborers with enthusiasm. But soon, competition for jobs became intense between white workers and the increasing number of Chinese workers. In some instances, mobs attacked Chinese immigrants. In 1882, Congress passed the Chinese Exclusion Act, which prohibited all Chinese laborers from immigrating to the United States. The act permitted only merchants, teachers, and certain other groups from China to come to the United States.

Ethnic background of Asian Americans

Figures are for 2000.
Source: U.S. Census Bureau.

The act was the first of numerous restrictions the U.S. government was to place on Asian immigration. The restrictions resulted in part because many American workers feared job competition from Asians, many of whom would work for low wages. In addition, some Americans argued that Asians could not be *assimilated* (incorporated) into American society because of their physical and cultural differences.

The second wave. Hawaii did not become a state until 1959. But in the late 1800's and early 1900's, it was the destination for several Asian immigrant groups. The first group was made up of Japanese workers. Between

1885 and 1894, an association of owners of Hawaiian sugar plantations recruited almost 29,000 Japanese as *contract laborers,* workers imported under an agreement to work for a particular employer.

After the Japanese fulfilled their contracts, most of them settled in Hawaii or in the Pacific Coast States of California, Oregon, and Washington. They worked first as farm hands and later grew vegetables on land they purchased or rented.

In the early 1900's, the Japanese population in the Pacific Coast States began to face the same opposition that had arisen against Chinese workers. In 1905, an organization that later became the Asiatic Exclusion League was established in California to work toward halting the immigration of Japanese people and other Asians. In 1908, the United States and Japan reached an understanding that became known as the *gentlemen's agreement.* The agreement restricted new Japanese immigration to the relatives of immigrants who had already settled in the United States. The gentlemen's agreement was not a law, and it was never put into writing. Japan cooperated voluntarily.

Arrivals of the early 1900's. The Hawaiian plantation owners began looking for other sources of labor in the early 1900's. Their Japanese workers had organized labor unions and frequently went on strike, demanding higher wages and better living conditions. The plantation owners turned to Korea, where the people had recently suffered through war and famine. During the early 1900's, the Hawaiians recruited more than 7,000 Korean laborers. But Korean immigration halted in 1905. Japanese workers had complained to their government that Korean workers were being used as strikebreakers. Japan, then in the process of taking control of Korea, put pressure on the Korean government to stop immigration to Hawaii. Most Koreans in Hawaii remained there. A small group migrated to the U.S. Pacific Coast.

In 1906, the plantation owners began bringing in workers from the Philippines. By 1931, about 110,000 Filipino laborers had arrived. During the early 1900's, a small number of Filipinos went to Alaska for seasonal work in the fishing industry. Others found agricultural work in such states as California and Oregon.

Groups of immigrants from India began arriving in the United States in the early 1900's. Most of the immigrants were young men from farm households in search of job opportunities. They arrived by ship in British Columbia, Canada, and then many made their way south into the United States. Most of them found work in lumber mills in Washington state or on farms in central California. Like other Asians before them, they faced opposition from local citizens. In 1907, a mob in Bellingham, Wash., rioted against Asian Indian sawmill workers. The mob attacked the homes of the Asians and drove the immigrants out of town. Most of the immigrants fled to Canada.

Asian immigration halted. In 1917, Congress passed one of the country's most restrictive immigration laws. The law prohibited immigrants from an area known as the Asiatic Barred Zone from coming to the United States. This area included most of Asia and a majority of islands in the Pacific Ocean.

The Immigration Act of 1924, which took effect in 1929, excluded any Asians who had not been barred by the 1917 law. The legislation closed the doors of the country to Asians—with one exception. People from the Philippines were allowed entry. At that time, the Philippines was a U.S. possession, so Filipinos were not considered foreigners. However, the Tydings-McDuffie Act of 1934 limited immigration from the Philippines to an annual quota of 50.

Japanese internment. Japan's surprise attack on the U.S. military base at Pearl Harbor, Hawaii, on Dec. 7, 1941, caused the United States to enter World War II. It also stirred hostility against Japanese people in the United States. Many Americans associated Japanese Americans with the Japanese pilots who had destroyed U.S. Navy ships.

Visual Communications

Filipino farm laborers, *above,* were among Asian immigrants of the early 1900's. During that period, thousands of Filipinos arrived to do agricultural work.

AP/Wide World

A Japanese American family is confined in a detention camp. In the early 1940's, during World War II, all West Coast residents of Japanese ancestry were forced into such camps.

In February 1942, President Franklin D. Roosevelt issued Executive Order 9066, which authorized military commanders to designate military areas from which "any or all persons may be excluded." The military chose to establish curfews for Japanese Americans, to remove all people of Japanese ancestry from the West Coast and southern Arizona, and to confine them in detention camps until their loyalty could be determined. About 110,000 Japanese were confined in 10 detention camps scattered over seven states: Arizona, Arkansas, California, Colorado, Idaho, Utah, and Wyoming. They lost their homes and their jobs as a result.

Today many scholars believe these restrictive measures against Japanese Americans were both unnecessary and discriminatory. However, the Supreme Court of the United States upheld the curfew in 1943 and the evacuation order in 1944, both on grounds of military necessity. But in another decision in 1944, the court ruled that holding admittedly loyal U.S. citizens in detention camps against their will was unlawful.

About 800 young Japanese Americans from the camps volunteered and served in the U.S. armed forces during the war. Most of them were part of the U.S. Army's 442nd Regimental Combat Unit. The unit fought bravely in Europe and suffered many casualties. Public opinion changed as Japanese Americans showed their loyalty to the nation.

In 1948, Congress passed the Japanese American Evacuation Claims Act. The law authorized a maximum payment of $2,500 to individual Japanese Americans as compensation for what they had lost while confined.

In 1980, Representative Norman Y. Mineta of California and Senator Daniel Inouye of Hawaii sponsored a bill that resulted in the establishment of the Commission on Wartime Relocation and Internment of Civilians. After holding numerous hearings across the country, the commission recommended that the president offer a national apology to Japanese Americans. It also called for a compensatory payment of $20,000 to surviving Japanese Americans who had been in the camps. These and other commission recommendations became law under the Civil Liberties Act of 1988.

Restrictions lifted. Although World War II brought suffering to many Japanese Americans, it also brought about the first easing of U.S. restrictions on Asian immigration. Because China was fighting as an ally of the United States, many people felt that Chinese immigrants should no longer be barred from the country. In 1943, the government lifted the ban on Chinese immigration and also allowed Chinese immigrants to become citizens. This was the first time that foreign-born Asians were granted the right to U.S. citizenship. In 1946, the government extended similar rights to Filipino and Asian Indian immigrants.

In 1952, Congress passed the Immigration and Nationality Act, also called the McCarran-Walter Act. This law essentially retained the Asiatic Barred Zone provision, but it did allow very limited immigration from the countries within the zone. It extended to all Asian immigrants the right to become U.S. citizens.

The Immigration Act of 1965 eliminated the Asiatic Barred Zone. After 1965, large numbers of Asians started moving to the United States, particularly from China, South Korea, and the Philippines.

Arrivals of the late 1900's. Millions of Southeast Asians have come to the United States since the mid-1970's. Most of them fled their homelands as a result of the Vietnam War (1957-1975). The first wave to arrive were Vietnamese political refugees who had worked for the U.S. government or U.S. companies. For the most part, they were educated, skilled workers. Most of the second wave were rural people from Cambodia and Laos, who had less education and fewer job skills.

About three-fourths of the Southeast Asian immigrants settled in 10 states: California, Florida, Massachusetts, Minnesota, New York, Pennsylvania, Texas, Virginia, Washington, and Wisconsin. The initial response in most communities where the refugees settled was one of sympathy. But in some cases, conflicts arose with local residents when the newcomers began to move into the labor force. Many Vietnamese refugees, for example, found jobs in the shrimp fishing industry in Texas, Mississippi, and other Gulf Coast States. Local fishing crews accused the Southeast Asians of setting too many traps, fishing in areas claimed by American crews, and other offenses. Fighting often broke out, and vandals on both sides damaged their rivals' boats and fishing nets.

Asian Americans today

Asian Americans are one of the fastest growing minority groups in the United States. Between 1990 and 2000, the number of Asian Americans increased by 48 percent. During that period, the percentage of increase of Asian Americans was second only to that of Hispanic Americans, whose numbers increased by 58 percent. In spite of their growth, however, Asian Americans still make up less than 4 percent of the population.

Like other minorities, Asians face problems of acceptance in American society. Also like other minorities, Asians struggle against inaccurate images that many people have of them. On one hand, for example, many books and motion pictures portray Asians as either sinister villains or meek servants. On the other hand, sociologists have referred to Asians as the "model minority." The label implies that all Asians have achieved success through discipline and hard work and thus other minorities should imitate them. However, although many Asian Americans are successful, many are not.

Education levels of Asian Americans vary widely, for example. A higher percentage of Asian Americans receive doctorates every year than either blacks or Hispanics. Yet many recent Southeast Asian immigrants have little or no formal education and few job skills.

Income levels also differ greatly. The median household income among Asian Americans is higher than that for the U.S. population as a whole. But it is also true that a higher percentage of Asians than whites live in poverty. And Asian American household income often includes the wages of several people. Many Asian Americans operate small businesses, primarily restaurants, grocery stores, and dry cleaners. Often, the whole family is involved in the business, and some members may work 12 to 14 hours a day.

Lack of English language skills is a major problem facing many recent Asian immigrants. Until these Asian Americans are able to speak English well, limited job opportunities will be available to them.

Joseph Nettis, Tony Stone Images

An Indian restaurant is an example of the many small businesses owned and operated by Asian Americans today. Often, several members of a family work long hours to keep the business running.

The efforts to learn English and to become a part of American culture have led to another problem, particularly for young Asians in families of recent immigrants. In attempting to become part of American culture, these young Asians often put aside the language and cultural traditions of their ancestors. As a result, they find themselves in conflict with their parents' generation. And they do not find complete acceptance in American society. They are left feeling that they are on the fringes of two societies and do not belong to either. This conflict eases over time as families become more Americanized. But it is something every immigrant group experiences upon coming to a new country. Hyung-chan Kim

Asian Development Bank (ADB) lends money to developing countries of Asia to promote their economic growth. A country must be an ADB member to borrow from the bank. The ADB also lends to—and invests in—private enterprises in Asia. The bank was established by the United Nations Economic Commission for Asia and the Far East. The ADB has about 50 member countries, including both developed and developing nations. Membership is open to countries that belong to the United Nations or to one of its specialized agencies. A non-Asian nation must be economically developed to become a member of the ADB.

When a country joins the ADB, it pledges a sum of money to the bank. Money also comes from voluntary donations by member nations. The ADB has loaned money for the development of agriculture, energy resources, and industry and for many other programs. The ADB started operations in 1966. It has headquarters in Manila, the Philippines.

Asimov, *AZ ih mahf,* **Isaac** (1920-1992), was an American author. He wrote about 400 books for young people and adults, mostly nonfiction emphasizing science and technology. However, he became best known for his science fiction. Many of Asimov's short stories and novels feature robots as characters. Several were collected in *I, Robot* (1950). His popular *Foundation* series of science-fiction novels includes *Foundation* (1951), *Foundation and Empire* (1952), *Second Foundation* (1953), *Foundation's Edge* (1982), *Foundation and Earth* (1986), *Prelude to Foundation* (1988), and *Forward the Foundation* (published in 1993, after his death). He also wrote *Fantastic Voyage* (1966) and *The Gods Themselves* (1972).

Asimov's nonfiction is notable for making complicated material understandable to the general reader. These works include *Asimov's New Guide to Science* (1984). He also wrote on history, humor, William Shakespeare, and the Bible. He wrote two volumes of autobiography, *In Memory Yet Green* (1979) and *In Joy Still Felt* (1980).

Asimov was born on Jan. 2, 1920, in Petrovichi, Russia, near Smolensk. When he was 3 years old, his family moved to New York City. He taught biochemistry at Boston University from 1949 to 1958 before becoming a full-time writer. He died on April 6, 1992. Neil Barron

Askia Muhammad, *AS kee ah* (1441?-1538), also called Askia I or Askia the Great, ruled the Songhai Empire in western Africa during its height. He was the first of several Songhai kings named Askia. Askia became king in 1493 when he overthrew Bakori Da'a, the son of Sunni Ali (see Songhai Empire). Askia seized large territories from the Mali Empire, conquered the Hausa states, and turned Saharan Berber towns into Songhai colonies. He encouraged the spread of Islam in West Africa and modeled his empire's laws on those of Islam. His eldest son, Askia Musa, overthrew him in 1528.

Askia Muhammad died on March 2, 1538, in Gao, the Songhai capital. Many people visit his huge tomb in Gao, in present-day Mali. Kevin C. MacDonald

Asmara, *az MAHR uh* (pop. 358,100), is the capital and largest city of Eritrea. It lies in central Eritrea, about 40 miles (64 kilometers) west of the Red Sea (see Eritrea [map]). The city has areas of treelined streets, expensive homes called villas, and large public buildings. It also has slum areas. A Roman Catholic cathedral, a large Eastern Orthodox church, and a major mosque stand near the city center. Many buildings in Asmara date from the early 1900's, when Eritrea was a colonial possession of Italy. The city's industries include tanning, textile production, and processing of agricultural goods. A railroad connects Asmara with Massawa, a port on the Red Sea. The city is the home of the University of Eritrea.

The site of Asmara was a small village until the late 1800's. It became the center for the Italian colonial government in 1897. The United Kingdom occupied Asmara from 1941 to 1952, when Eritrea became part of Ethiopia. In 1993, following a 30-year civil war between Eritrean rebels and the Ethiopian government, Eritrea gained formal independence. Stephen K. Commins

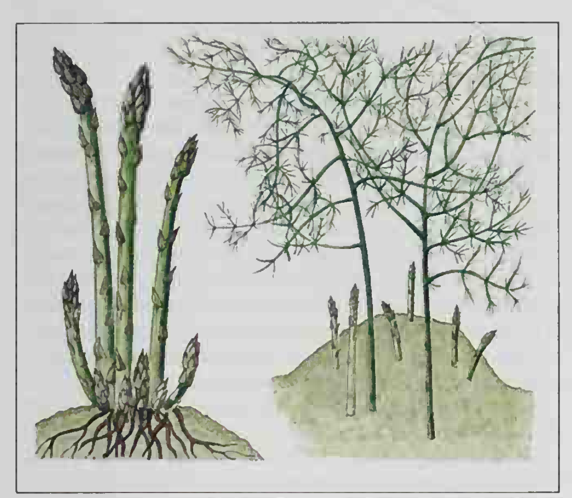
Asoka. See Ashoka.

Asp is the name of a cobra found in Egypt. It is also called the Egyptian cobra. The hood of this poisonous snake lacks the spectacular markings of the Indian cobra. The ancient Egyptians worshiped the asp. It is believed that Cleopatra committed suicide by holding an asp against her body. Others claim the snake was the horned viper, sometimes called an asp. See also Cleopatra; Cobra; Snake.

Albert F. Bennett

Scientific classification. Asps belong to the family Elapidae. They are *Naja haje.*



WORLD BOOK illustration by Richard Lewington, The Garden Studio

Asp

Asparagus is a nutritious green vegetable. People eat the young *shoots* (stems) of the asparagus plant. These shoots are called *spears.* Asparagus is an excellent source of protein, vitamins, and minerals. For the best taste and highest nutritional value, fresh asparagus should be cooked gently until soft, but it should remain a brilliant green in color.

Asparagus plants originated in the Mediterranean region and in Africa. They grow best in moderate climates and in loose, moist, sandy soil. In the United States, most asparagus is produced in California, New Jersey, and Washington.

Asparagus is a *perennial* plant—that is, it can live for several years without replanting. Most of the commercial asparagus crop is grown from seedlings planted in early spring. As the plants grow, they develop a root system called the *crown.* The crown consists of fleshy roots that store food and underground stems called *rhizomes.* As the soil temperature rises, buds on the rhizomes grow through the soil and become the spears. If the spears are not harvested, they develop into tall, mature plants with feathery leaves. Generally, asparagus plantings are first harvested during the second or third year, depending on the area in which they are grown, when

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd

Two types of asparagus. People eat edible asparagus, *left.* Florists use asparagus fern, *right,* in decorations.

the roots are able to store large amounts of food. In some cases, such properly established plantings may continue to produce well for 15 to 25 years.

The *asparagus fern* is a kind of asparagus used in floral arrangements. It also is a good house plant.

Albert Liptay

Scientific classification. Asparagus belongs to the lily family, Liliaceae. Edible asparagus is *Asparagus officinalis.* The asparagus fern is *A. plumosus.*

Aspartame. See **Artificial sweetener.**

Aspen, Colorado (pop. 5,914), once a rich silver-mining center, is now a year-round resort. It lies at an altitude of 7,930 feet (2,417 meters) on the Roaring Fork River in west-central Colorado (see **Colorado** [political map]). It is one of the most popular ski centers in the western United States, with four mountains for downhill skiing and about 40 miles (64 kilometers) of trails for cross-country skiing. In summer, the Aspen Institute for Humanistic Studies holds seminars for business people. The Music Associates of Aspen runs a 9-week Aspen Music Festival, and Ballet/Aspen sponsors a 5-week dance festival. Mary Eshbaugh Hayes

Aspen is the name of three species of medium-sized poplar trees found in North America, Europe, Asia, and Africa. Aspens have smooth, light-colored bark. Their leaves have long, flattened stalks and may be triangular, heart-shaped, or round. In fall, aspen leaves turn brilliant yellow.

The most common type of aspen in North America is the *quaking aspen.* It is found from eastern Canada to Alaska, across the Northeastern and Great Lakes states, and in western mountains south into Mexico. Its nearly round leaves have fine-toothed edges. The *bigtooth aspen* grows throughout southeastern Canada and eastward from Minnesota and Iowa in the United States. It is found primarily in low-lying areas with sandy soils. Its leaves are egg-shaped and have coarse-toothed edges. The *European aspen* is found in Europe, North Africa, western Asia, and Siberia. Its leaves are round or oval with notched edges.

Aspens require open, sunny places to reproduce. In forest areas that have been opened up by fire, disease, or other disturbances, aspens grow rapidly and often become the dominant species in a few years. Later, they are generally replaced by trees that grow well in shade.

Aspen wood is used primarily to make pulp for paper. The wood is also used to make matchsticks, boxes, and crates. Michael J. Baranski

Scientific classification. Aspens belong to the willow family, Salicaceae, and the genus *Populus.* The quaking aspen is *Populus tremuloides.*

See also **Poplar; Tree** (Familiar broadleaf and needleleaf trees [picture]).

Asphalt, *AS fawlt,* is a black cementlike substance that is found in most crude petroleum. It has hundreds of uses. It is used to pave streets, highways, and airfields; to make roofing, waterproofing, and insulating materials, and floor tiles; and to line reservoirs, waste storage ponds, dams, and irrigation canals. Asphalt is also used in varnish and inks. Asphalt coatings also protect underground pipelines from corrosion.

Asphalt is *thermoplastic.* That is, it softens and becomes a liquid when heated, and returns to a solid when cooled. Asphalt wears well, is highly waterproof, and is unharmed by most acids and salts.

Asphalt production. Asphalt is separated from crude petroleum by refining methods that also produce gasoline, kerosene, and other products. Usually, gasoline and other products with low boiling points are removed by a *distillation* (boiling) process. The oil that remains is commonly called *topped crude.* Topped crude may be used as a fuel oil, or further refined to asphalt or other products. By varying the refining processes, different kinds of asphalt may be obtained. For example, *blown* or *oxidized* asphalts are made by blowing hot air through topped crude. They are widely used for roofing, enamels, and other industrial applications. Most topped crude is refined to produce *asphalt cement,* a semisolid asphalt used for paving.

Asphalt also occurs in natural deposits in pits, lakes, and rocks. But only a small part of the asphalt used in the United States comes from natural deposits. Some natural deposits found in pits and lakes are pure, but most deposits have become mixed with mineral matter, water, and other substances. One of the best-known deposits is Pitch Lake on the island of Trinidad in the Caribbean Sea. Sir Walter Raleigh discovered this 114-acre (46-hectare) bed in 1595. One of the largest deposits of asphalt is in Lake Guanoco in Venezuela, near the Gulf of Paria. The deposit covers about 1,000 acres (400 hectares). *Uintaite* or *gilsonite,* a solid form of asphalt, is found in Utah and Colorado.

Paving with asphalt. Asphalt is used mainly to pave streets, highways, and airports. Over 90 percent of all paved roads in the United States have asphalt surfaces. *Blacktop* is the common name for many types of asphalt paving. Asphalt pavements are made in several ways. But usually, asphalt cement is mixed with *mineral aggregates,* such as crushed stone, gravel, and sand. These aggregates vary in size. The largest particles are usually about $\frac{3}{4}$ inch (19 millimeters) in diameter.

The aggregates are blended, dried, and heated to about 300 °F (149 °C) in a paving plant. *Hot mixes* are prepared by adding hot asphalt cement. Paddles mix the asphalt with the aggregates in a *pugmill mixer.* The mix

contains only about 5 to 10 percent asphalt by weight.

A paving machine spreads the mixture evenly on the roadbed, and a roller flattens it into a smooth, hard pavement. *Cold mixes* are made with liquid asphalt. This is a blend of asphalt cement and a light petroleum *solvent* (a substance that can dissolve other substances). Cold mixes can also be made by carefully blending asphalt cement with water. Cold mixes often can be prepared directly on the roadbed because little or no heating is needed in their preparation.

Surface treatment is used to resurface pavements or to pave lightly traveled roads. Hot asphalt cement or liquid asphalt is sprayed evenly over the roadway surface. Mineral aggregates are then spread over the surface and rolled into the asphalt. Geoffrey E. Dolbear

See also **Petroleum; Road** (picture: Blacktopping).

Asphyxiation, *as FIHK see AY shuhn,* is a condition that occurs when breathing stops. During breathing, the lungs provide the blood with oxygen needed to sustain life. Without oxygen, the brain, heart, and other vital organs fail to function. A person loses consciousness when too little oxygen reaches the brain. The heart stops beating if it receives too little oxygen.

Common causes of asphyxiation include drowning, choking, receiving an electric shock, and inhaling poisonous fumes. A person who is not breathing often requires the mouth-to-mouth form of *artificial respiration,* also called *rescue breathing* (see **First aid** [Restoring breathing]). First aid for a person choking on food or other objects includes the application of upward thrusts to the middle of the abdomen. This technique is known as the *Heimlich maneuver* (see **First aid** [Choking]). A person whose heart has stopped beating requires *cardiopulmonary resuscitation,* or *CPR* (see **Cardiopulmonary resuscitation**). Brian J. Sproule

Critically reviewed by the American Red Cross

Aspidistra, *AS puh DIHS truh,* is a widely cultivated house plant. The aspidistra is native to Asia. Because it grows under adverse conditions, it is also known as *iron plant* and *barroom plant.* It has numerous long, glossy leaves. The leaves may be solid green, striped with white, or spotted with yellow. Aspidistras bear purplish-brown flowers at the base. Kenneth A. Nicely

Scientific classification. The aspidistra is in the lily family, Liliaceae. It is *Aspidistra elatior.*

Aspin, Les (1938-1995), was United States secretary of defense under President Bill Clinton in 1993 and 1994. Before his appointment, Aspin had served since 1971 in the House of Representatives as a Democrat from Wisconsin. He had also served as chairman of the House Armed Services Committee almost continuously since 1985. As secretary, Aspin helped plan major reductions in U.S. military bases and personnel. While he was secretary, bans were lifted on women flying combat missions and serving on combat naval vessels. In addition, regulations designed to prevent homosexuals from serving in the armed forces were relaxed.

Leslie Aspin, Jr., was born in Milwaukee. In 1956, he enrolled at Yale University, where he joined the Reserve Officers Training Corps. He received a bachelor's degree from Yale in 1960 and a bachelor's degree from Oxford University in England in 1962. Aspin completed a Ph.D. degree in economics at the Massachusetts Institute of Technology in 1965. From 1966 to 1968, he served as an Army captain and as an analyst for the Department of Defense. Barton Gellman

Aspirin, also known as *acetylsalicylic acid,* is one of the most commonly used drugs in the world. It helps relieve pain from headaches and arthritis, and reduces fever from infections. It also reduces inflammation due to illness or injury. Aspirin interferes with blood clotting, and thus it is useful in preventing heart attacks, strokes, and other disorders that involve blood clots.

Aspirin is a white, odorless powder with a bitter taste. Its chemical formula is $C_9H_8O_4$, and it belongs to the group of compounds called salicylates. Aspirin achieves at least some of its effects by blocking the formation of certain *prostaglandins* (hormonelike chemicals found throughout the body). See **Prostaglandin.**

Aspirin is relatively safe when taken at recommended dosage levels. But it can irritate the stomach lining and cause bleeding. A few people are allergic to aspirin and become ill if they take it. Aspirin should not be given to children with chickenpox or influenza. Its use during these illnesses has been associated with a serious condition called *Reye's syndrome* (see **Reye's syndrome**).

For centuries, people throughout the world had used willow bark to relieve pain and fever. The bark contains a chemical that is converted by the body to a salicylate. But it was not until the 1800's that aspirin was made in a laboratory. Charles Gerhardt, a French chemist, synthesized aspirin in 1853. Its medicinal value was not fully recognized until 1899, when Heinrich Dreser, a German scientist, wrote about its effectiveness.

The drug is sold under the generic name *aspirin* in the United States and *acetylsalicylic acid,* or *ASA,* in Canada. It is the active ingredient in many trade-named, nonprescription pain relievers. N. E. Sladek

Asquith, *AS kwihth,* **Herbert Henry** (1852-1928), served as prime minister of the United Kingdom from 1908 to 1916. His ministry was significant for the Old Age Pension Act (1908), the National Insurance Act (1911), and the Parliamentary Act (1911), which restricted the power of the House of Lords. David Lloyd George replaced Asquith as both Liberal Party leader and as prime minister in 1916. A breach between the two men helped bring about a decline of the Liberal Party after World War I ended in 1918 (see **Lloyd George, David**).

Asquith was born in Morley, Yorkshire. He served as the United Kingdom's chancellor of the exchequer from 1905 to 1908. In 1925, he became the Earl of Oxford and Asquith. Keith Robbins

Ass. See Donkey.

Ass, Wild. See Onager.

Assad, *ah SAHD,* **Bashar al-,** *bah SHAHR uhl* (1965-), became president of Syria in July 2000. His name is also spelled Bashar al-Asad. He took over the presidency following the death of his father, Hafez al-Assad (also spelled Hafiz al-Asad), Syria's leader since 1970. Hafez al-Assad began preparing Bashar to be his successor after the death in 1994 of Bashar's older brother, Basil. Basil had been expected to assume the presidency.

Bashar al-Assad was born in Damascus. Assad received a medical degree from the University of Damascus in 1988. He trained in *ophthalmology* (the study of diseases of the eye) at the Tishrin military hospital in Damascus from 1988 until 1992. He moved to England in 1992 to complete a medical residency program.

In 1994, Bashar's brother Basil was killed in a car accident. Bashar was called back to Syria to train to take over the presidency. He attended the military academy at Homs, north of Damascus, earning the rank of colonel. After his father's death, Assad was promoted to lieutenant general and made commander in chief of the armed forces. He also became head of the ruling Baath Party. As'ad AbuKhalil

Assad, *ah SAHD,* **Hafez al-** *HAH fehz uhl* (1930-2000), served as president of Syria from 1971 until his death in 2000. A military leader, he seized power from Syria's radical government in 1970. He was elected president the next year. His name is also spelled Hafiz al-Asad.

Assad sought to make Syria a strong regional power and the leader of the Arab struggle against Israel. In 1973, Syria and Egypt fought a war against Israel in an unsuccessful attempt to regain Arab land Israel had occupied in 1967. After the war, tension continued between Syria and Israel. Assad's government joined Arab-Israeli peace negotiations in 1991. In 1976, the government sent troops to help end a civil war in Lebanon. Most of the fighting ended in 1991. Also under Assad, Syrian troops helped allied forces defeat Iraq in the Persian Gulf War of 1991. Assad was a member of the Baath socialist party and of Syria's minority Alawite Muslim sect. In 1982, his government crushed a rebellion by militant Sunni Islamic opposition.

Assad was born in Al Qardahah, Syria, near Latakia. He attended the military academy in Homs and graduated from the air force academy in Aleppo. He was commander of the Syrian Air Force and minister of defense when he seized power in 1970. Michel Le Gall

Assassination is the murder of a person who holds a position of public importance. Ordinarily, assassinations are committed for one or more of three reasons: to gain revenge, to earn a reward, or to remove a political enemy from office. The assassination of a ruler has often been applauded. Brutus, one of the assassins of Julius Caesar, was considered a hero by many Romans.

The assassination of Archduke Ferdinand of Austria, in 1914, was one cause of World War I. The series of assassinations committed by the Black Dragon Society in Japan in the 1930's threw control of the government into the hands of the Japanese Army. Four presidents of the United States have been assassinated: Abraham Lincoln in 1865, James A. Garfield in 1881, William McKinley in 1901, and John F. Kennedy in 1963.

The word *assassination* comes from *assassins* or *hashshashin* (hemp-eaters), a band of Muslims in Persia and Asia Minor in the 1100's. They smoked a drug called *hashish,* which is made from the hemp plant, and killed their enemies while under its influence. Stephen Goode

Assault and battery is a legal term that involves a physical threat and act. An act of assault puts the victim in fear of bodily harm. Spoken threats are not assaults, because there must be some physical act. Raising a club or drawing back a fist is considered to be an assault, even if no actual blow follows. One who levels a gun at a crowd of people may be found guilty of assault against every person in the crowd. Battery pertains to the actual blow, or other physical injury. The two offenses usually occur together and are usually punished as one. No assault results if a person has a right to threaten or inflict harm. People can legally remove intruders from their homes with whatever force is necessary.

Parents may use force in punishing children. But they become guilty of assault and battery if they punish too roughly. Assault and battery are crimes punishable by fine or imprisonment. The offender may also be sued for damages by the victim. Charles F. Wellford

Assaying, *uh SAY ihng,* is any process used to determine the amount of one or more metals or valuable minerals contained in substances. These substances include ore samples, *ingots* (molded masses of metal), and *alloys* (mixtures of metals). Assaying tests show the purity of precious metals and whether mineral beds will be profitable to mine. The method used depends on the substance analyzed. The two general methods are (1) *dry,* or *fire,* assaying and (2) *wet* assaying.

Dry assaying. In this method, the sample is melted to separate the metals it contains. For example, an ore sample containing gold and silver is mixed with lead oxide and other substances. This mixture is put into a crucible of fire clay and set inside a furnace to be melted. The hot lead oxide produces lead, which picks up the gold and silver and carries them to the bottom of the crucible. The impurities and other substances float to the top. The remaining alloy of lead, gold, and silver is placed in a porous cup and melted in a furnace. The lead turns to lead oxide, which evaporates. The gold and silver remain as a mixture called *dore metal.* The silver is dissolved in nitric acid to separate it from the gold.

Wet assaying. Assayers use various chemicals to dissolve and separate the metals contained in a sample. The amount of a metal in a sample is determined by weighing the compound the metal has formed with the added chemicals. In some tests, the metals can be extracted from these chemical compounds and then weighed in pure form. Another wet assaying method involves measuring the quantity of some agent that reacts with the chemical dissolved out of the ore or alloy.

An *assay office* is a laboratory where assaying is performed. Many mining and metallurgical companies have them. The United States Mint runs an assay office in New York City that assays and purchases gold and silver bullion. Canada maintains a similar bureau under the supervision of the Royal Mint. Baki Yarar

Assemblies of God is the largest Pentecostal religious denomination in the world. Its official name is The General Council of the Assemblies of God. It developed from a revival movement during the early 1900's and was organized in Hot Springs, Arkansas, in 1914.

The denomination teaches that the Bible is *infallible* (cannot be wrong). It also teaches the fall and redemption of human beings, a life of separation from the world, divine healing through prayer, the return of Jesus Christ and His reign, and eternal punishment for the unsaved. The church teaches that Christians should seek to be filled with the Holy Spirit. The initial physical evidence of this comes when people *speak in tongues* (speak in a language they never learned). Believers are baptized by *immersion* (dipping into water). The church observes the ordinance of the Lord's Supper.

The Assemblies of God churches direct their own local affairs. A General Council meets every two years and supervises activities throughout the world in mis-

sions, publications, and education. The General Council consists of all ordained ministers and a lay delegate from each affiliated church. The denomination is organized into 57 districts, including 10 ethnic districts in the United States and Puerto Rico. It has about 2 million members. Headquarters are in Springfield, Mo.

Critically reviewed by The General Council of the Assemblies of God

Assembly line is a group of work areas, called *stations,* arranged in a certain order to make a product. Each station performs a given task on a unit of a product—such as inserting, tightening, or inspecting a part—and then passes it to the next station. When a unit reaches the end of the line, it has passed all the stations and has become a finished product. Each station consists of the machines, workers, tools, and parts required to do its assigned task. In some cases, industrial robots do simple assembly-line tasks (see **Robot**). Many factories also use a *conveyor belt* to carry a unit from station to station (see **Conveyor belt**).

Assembly-line production relies on the use of *interchangeable parts*—that is, all the pieces of a particular part type are identical. Therefore, it does not matter which piece is selected for a unit of product to be made because each piece will fit. Assembly lines also depend on *division of labor,* in which small portions of a job are divided among different workers. In this way, relatively unskilled workers can learn their job quickly and contribute to the manufacture of even complex machinery. Assembly lines enable large quantities of products to be made at low cost. Ronald G. Askin

Assessment is the process of assigning a cash value to property for the purpose of taxation. Assessed property may include land, buildings, business equipment, and inventory. The term *assessment* also refers to the amount of tax that is levied on a property. The amount of tax is based on the assessed value of the property (see **Property tax**). In most cases, assessments are determined by state or local officials called *assessors.* Assessors may be elected by the voters or appointed by the state or local government.

Assigning a fair and uniform value to property is the chief goal of assessment. Assessors try to determine what property would sell for if it were offered on the open market for a reasonable time and if both buyer and seller were well informed. Assessors make such determinations largely by collecting information about the sales prices of similar property recently sold.

Several problems make it difficult to make a fair estimate of value. One problem is that nearly all properties are different. For example, a large house on the corner differs from a small house in the middle of the block. If recent sales involve only small houses, the assessor must use that information to estimate the value of a large house. Another problem is that sales information quickly grows out of date. Prices more than a year old are probably not a useful guide to current values.

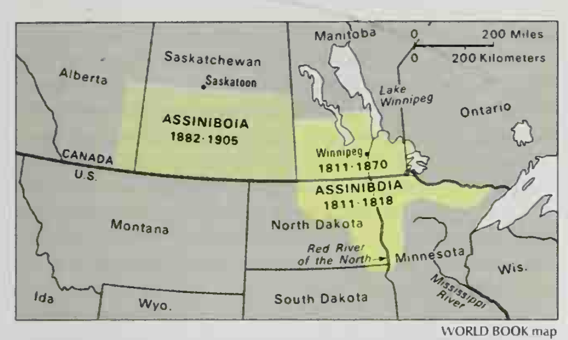
Still another problem is that much property, such as office and medical buildings, is rented rather than sold. The assessor must use information on rental income and expenses to estimate what the building is worth to the owner. Some property—such as factories, power plants, and railroad tracks—is neither rented nor sold. To assess such property, the assessor must collect information on the cost of buying vacant land and building a similar structure. John M. Clapp

Assignment is the legal term for the transfer of rights to property or money from one person to another. The person who makes the transfer is the *assignor.* The *assignee* receives whatever rights the assignor had. For example, if the assignor has the right to possess a piece of land, the assignee receives the right. If the assignor has only the right to collect rents from the land, the assignee receives only that right. People usually make assignments in writing. In some cases, a person may assign property that he or she expects to own. See also **Loan company**. Linda Henry Elrod

Assimilation, *uh SIHM uh LAY shuhn,* is the process by which cells convert food into living tissues. This process makes possible the growth and repair of living organisms. In human beings, assimilation begins when food is broken down into simple molecules in the stomach. This process is called digestion. The bloodstream absorbs the digested food and carries it to all parts of the body. Then, the digested food is assimilated by the cells for use in the growth and repair of the body. See also **Absorption and adsorption; Cell; Digestive system**. George B. Johnson

Assimilation, *uh SIHM uh LAY shuhn,* is the process through which one social and cultural group becomes part of another social and cultural group. For example, groups of people from many countries have settled in the United States. Most of these people gradually abandoned the way of life of their homeland, and adopted an American way of life. They learned the language, adopted the customs, and followed the traditions.

Assimilation may also occur when people move from one part of a country to another part. For example, farm people who move to a city become assimilated into the way of life of the city. A group that becomes assimilated does not necessarily adopt the new way of life completely. It may keep some of its old customs or modify some of the new customs while adopting them.



Sometimes, assimilation is prevented or slowed down because a majority group does not want contact with a minority group. Blacks, Jews, and other minority groups have often been forced to remain in *ghettos* (segregated living areas). In other cases, minorities have held to their way of life, and have deliberately avoided assimilation into the majority. The Amish of United States farm communities are an example (see **Amish**).

In industrial countries, minorities almost always become assimilated into the majority's way of life. But in developing countries, majorities sometimes become assimilated into a minority. This occurs when a minority is socially and economically more advanced or powerful than the majority. Wolf Heydebrand

Assiniboia, *uh SIHN uh BOY uh,* was the name of two territorial districts in what are now the United States and Canada. One district lay on either side of the Red River in both countries. The other district was mainly in the present-day province of Saskatchewan.

In 1811, the district along the Red River was granted to the Earl of Selkirk, a Scottish colonizer in Canada. He named the area after local Indians. Part of the district, which included much of what are now North Dakota

WORLD BOOK map

Assiniboia was the name of two historic areas of southern Canada and the Northern United States.

and Minnesota, was cut off when the 49th parallel became the U.S.-Canadian boundary in 1818. The rest disappeared when the province of Manitoba was created in 1870. See **Selkirk, Earl of; Manitoba** (The Red River Colony).

In 1882, a district in what was then the Canadian North West Territories was named Assiniboia. In 1905, it became part of Alberta and Saskatchewan. See **Saskatchewan** (North West Territories). J. M. Bumsted

Assiniboine Indians, *uh SIHN uh BOYN,* are a large Plains tribe who live in parts of Canada and the United States. Before Europeans came to North America, the Assiniboine lived near Lake Superior in what is now Ontario. During the late 1600's and the 1700's, they moved to what became Saskatchewan, Montana, and North Dakota. The name *Assiniboine* probably comes from a Chippewa word that means *one who cooks by the use of stones.* They boiled soup by dropping hot stones into a pot. In Canada, they are often called *Stonies.*

The Assiniboine were a nomadic people who moved about following buffalo herds. They lived in tepees made of buffalo hides and wore buckskin clothing. The men hunted game, especially buffalo and antelope, and the women gathered berries, fruits, and plants to eat. The Assiniboine formed bands of related families who camped and hunted together. Each band was headed by a chief and a council of elders. The tribe's religion centered on the pursuit of visions and on a ceremony called the *sun dance* (see **Sun dance**). The Assiniboine believed visions brought help from the gods.

The Assiniboine were originally a division of the Sioux Indians but separated from them before 1640. They then became allies of the Cree, who were enemies of the Sioux. During the late 1700's and early 1800's, smallpox wiped out nearly half the Assiniboine.

Today, about 3,500 Assiniboine live on the Fort Peck and Fort Belknap reservations in Montana. Another 3,500 live on nine small reserves in Alberta and Saskatchewan. Each reservation or reserve is governed by an elected tribal council. Some Assiniboine are farmers or ranchers. Many members of the tribe are poor and depend on economic aid from the government of the United States or Canada. Despite these problems, the people are proud of being Assiniboine, and many still speak their native language. Raymond J. DeMallie

Associated Press (AP) is one of the world's largest news-gathering services and one of two general news services in the United States. The other is United Press International (UPI). The AP distributes international, regional, and local news to media worldwide.

The AP is a nonprofit organization. It is owned and controlled by more than 1,500 daily newspapers in the United States. These members, along with 6,000 U.S. radio and television stations, receive news from the AP. News media in 111 other countries also subscribe to the service. The AP provides its news in five languages.

The AP offers daily news reports, features, photographs, and *graphics* (artwork). Most U.S. members receive news around the clock via satellite. Some radio stations receive AP audio newscasts. AP photographs are sent digitally via satellite or telephone line. Digital transmission is a method of sending sounds or pictures by converting them into electrical signals in the form of a *digital* (numerical) code. Some television stations also receive AP video graphics in digital form.

Six New York City newspapers founded the Associated Press in 1848. They began the service to save money on the gathering of news by telegraph. Today, the AP has about 230 news bureaus worldwide. Its headquarters are in New York City. Richard A. Schwarzlose

See also **News service.**

Association, in psychology, refers to one theory of how people learn things.The theory's three laws of association attempt to explain how a person *associates* (relates) experiences. These laws are: (1) the law of contiguity, (2) the law of similarity, and (3) the law of contrast.

The law of contiguity states that mental associations occur when two events take place close to each other in time or space. For example, teachers try to grade an examination soon after students take it. This helps students associate the correct answers with the questions while the examination is fresh in their minds.

The law of similarity states that a person is more likely to connect two things that are almost the same. For example, a child is more likely to associate a wagon with an automobile than with an airplane.

The law of contrast states that greatly differing things are likely to be associated. For example, it is easier to learn the differences between "hot" and "cold" than between "hot" and "warm."

Critics of the theory say it puts too much emphasis on the events associated and not enough emphasis on the person. Psychologists holding other views think that the ability of a person to understand the similarity or difference between things is also important in learning.

Few psychologists accept the associationist point of view completely. Most realize association takes place, but doubt it explains all learning. Allen Frances

Association for the Study of African-American Life and History conducts and promotes research and study of the black person's role in world history. The association collects writings and materials relating to African Americans and other ethnic groups. It promotes harmony and understanding among all people. The association has about 2,000 members, including historians, scholars, and students. It sponsors Black History Month and sets the national theme for the celebration. It also publishes *Negro History Bulletin* and *The Journal of Negro History.* Its subsidiary, the Associated Publishers, publishes books and a Black History Month kit. The

American historian Carter G. Woodson founded the Association for the Study of Negro Life and History in 1915. The association received its present name in 1998. Headquarters are in Washington, D.C. See also **Black History Month; Woodson, Carter Goodwin.** Critically reviewed by the Association for the Study of African-American Life and History

Association of Southeast Asian Nations (ASEAN) is an organization of 10 Southeast Asian countries—Brunei, Cambodia, Indonesia, Laos, Malaysia, Myanmar, the Philippines, Singapore, Thailand, and Vietnam. It promotes political, economic, cultural, and social cooperation among its members. Although ASEAN works for peace and stability in Southeast Asia, it is not a defense organization.

The members of ASEAN cooperate in such fields as population control, prevention of drug abuse, and scientific research. Teachers, students, and artists of the member nations exchange visits. In addition, the organization develops plans to promote tourism in ASEAN countries and to encourage programs of Southeast Asian studies. It works to reduce trade barriers among the members.

The foreign ministers of the member countries meet annually to determine ASEAN policy and to consider projects recommended by ASEAN committees. These committees deal with subjects ranging from food and agriculture to the mass media. They consist of experts and officials from the member countries and are responsible for putting ASEAN projects into effect. ASEAN's administrative body, the Central Secretariat, works to make sure that the policies of the organization are carried out. The secretariat is in Jakarta, Indonesia.

ASEAN was established in 1967 by Indonesia, Malaysia, the Philippines, Singapore, and Thailand. During the 1970's, cooperation increased among the member nations. The ASEAN heads of government met in 1976 for the first time and made several important agreements. The member nations agreed to share basic products during shortages and to gradually remove trade restrictions. They also decided to build an industrial project in each country. The leaders established the organization's Central Secretariat, as well as a council to settle disputes among the member nations.

Brunei became a member of ASEAN in 1984. Vietnam was admitted in 1995, Laos and Myanmar in 1997, and Cambodia in 1999. David P. Chandler

Assumption is the religious belief that a certain person was taken bodily into heaven. The belief is part of both Jewish and Christian tradition.

In Judaism, an assumption is called an *aliyah,* which means *ascent* or *going up.* In the Old Testament, or Hebrew Bible, there is only one specific reference to an assumption. In 2 Kings 2:1-13, God takes the prophet Elijah into heaven in a whirlwind. Other Jewish traditions based on Old Testament stories state that Enoch, the father of Methuselah, and the Israelite leader Moses ascended into heaven.

Belief in assumption is not found in the New Testament, but it became significant during the late Middle Ages, especially in the Western church. The Assumption of the Blessed Virgin is a doctrine of the Roman Catholic Church. It states that the body and soul of the Virgin Mary were taken into heaven. Pope Pius XII proclaimed the Assumption a church doctrine in 1950. Roman Catholics celebrate the Feast of the Assumption on August 15. Assumption is not a Protestant doctrine but has been accepted as a belief in the Eastern Orthodox Churches.

The Assumption of Mary has been a popular subject in painting. Many pictures portray Mary ascending to heaven with angels or bands of cherubs. A painting called *Assumption of the Virgin* by the Spanish artist El Greco appears in **Art and the arts.** Stanley K. Stowers

Assurbanipal. See Ashurbanipal.

Assyria, *uh SIHR ee uh,* was an ancient country on the upper Tigris River in Mesopotamia. It covered roughly the northern part of present-day Iraq. Assyria's civilization was similar in many ways to that of ancient Babylonia, its neighbor to the south.

The Assyrians have been called the *Romans of Asia.* Like the Romans, they were great conquerors. They won their victories in the Roman way, by superb organization, weapons, and equipment.

The land

Assyria was a land of rolling hills. The Tigris River and the small streams that fed it kept the valleys fertile. To the north rose the steep Armenian Mountains. On the east were the Zagros Mountains and the high hills of Iran. These mountainous lands did not attract the Assyrians much. But the lands to the south and west were better than their own. The rich lands of Babylonia and the fertile plains of western Mesopotamia and Syria lay open to the Assyrian conquerors. Assyria had a better natural climate for agriculture than Babylonia. It was cooler, and the rainfall was heavier. But irrigation was easy on the Babylonian plain and very hard in the Assyrian hills. Once started on the path of conquest, the Assyrians took much more than the fertile farmland next to them. The empire came to include mining land, forestland, and other kinds of land. But Assyria itself remained a farming country. Ancient Assyria also had plenty of good building stone, some timber, and a few minerals.

Way of life

The Assyrian people dressed in coatlike garments called tunics and wore sandals. The men wore their hair long, and many grew beards. Most men had short beards, but many high-ranking officials wore long beards that were squared at the bottom.

Most Assyrians worked for Assyrian rulers or for other powerful people. Farmers lived in small villages on estates and worked the land. They dug irrigation canals that channeled water to the farmland and helped control flooding. They lived in houses that had thatched roofs and walls made of intertwined branches and mud. Farmers raised livestock and produced milk and other dairy products. The most important crop was barley.

Assyria had few large cities. The most important were Assur, Nineveh, and Kalhu (also spelled Calah, but now called Nimrud). Most city dwellers were craftworkers or traders. Craftworkers made pottery, and objects out of gold, silver, bronze, ivory, and wood. High walls, guarded by archers, encircled the cities to protect residents from attack. Citizens grew fruits and vegetables in gardens and orchards just outside the city walls.

Some Assyrians roamed the countryside in seminomadic groups. These groups consisted mostly of runaway slaves, unsuccessful farmers, and people who had

been expelled from the cities. From time to time, bands of these people raided and looted the cities. Relations between the city dwellers and the seminomads were always tense. Monarchs always tried to strengthen control over the land as soon as they took the throne.

Assyria had only a few slaves. Most slaves were prisoners of war or people who could not pay their debts. Some Assyrians sold their wives and children into slavery to clear their debts.

Language and literature. A variety of peoples lived in Assyria. As a result, a number of different languages were spoken there. Until about 1000 B.C., however, writing was done only in a Semitic language related to modern Hebrew and Arabic.

The early Assyrians used a writing system called *cuneiform* that was developed by the Babylonians. It consisted of wedge-shaped symbols on clay tablets. The writings dealt with religion, literature, medicine, history, and other subjects. Assyrian kings collected the clay tablets in huge libraries. There, librarians carefully indexed the tablets and kept them on shelves.

In the 1850's, archaeologists discovered two major libraries in Nineveh, each containing thousands of clay tablets. King Sennacherib, who reigned in Assyria from 704 to 681 B.C., assembled one of the libraries. His grandson, King Ashurbanipal, assembled the other, which included Assyrian, Babylonian, and Sumerian tablets. Most of the tablets from Ashurbanipal's library are now in the British Museum in London.

The Assyrians also wrote legal texts. The *Middle Assyrian Laws* date from about 1400 B.C. Like the Babylonian Code of Hammurabi, these laws consist of examples of cases, each with its judgment. But the Assyrians imposed harsher penalties on lawbreakers than the Babylonians did.

Most later Assyrians probably spoke Aramaic. Much of the writing was done in Aramaic script, probably written in ink on parchment. Aramaic did not completely replace the cuneiform script, however. Both survived as written languages until the end of the Assyrian Empire, but they were used for different purposes. The historical and religious texts were written in cuneiform. But Assyrians used Aramaic for their everyday business. Most of the Aramaic parchments decayed long ago, so scholars have learned little about Assyria's trading activities during its last few hundred years.

Religion. Assyrian religion was closely related to the earlier Sumerian and Babylonian religions. Assyrians believed that many gods directed human destiny and controlled the sky, the earth, water, storms, and fire. The Assyrians also believed in good and evil spirits, and in magic.

Their religion differed from the earlier religions in some ways. The chief god of Assyria was Ashur, or Assur, whose name was the same as the Assyrians' name for their country and most important city. The chief Babylonian god was Marduk. Babylonian kings were not religious leaders. They could enter the temple only once a year under special circumstances. But the Assyrian king served as both the ruler and the chief priest, and the people considered him Ashur's governor on the earth.

Assyrians worshiped other gods, including Nabu, the god of learning and patron of *scribes* (writers); Ninurta,

The Metropolitan Museum of Art, New York City, Gift of John D. Rockefeller, Jr., 1932

A winged lion of the 800's B.C. stood in front of the palace of Ashurnasirpal II. It was supposed to ward off evil.

god of war; and Ishtar, the goddess of love. The goddess Ishtar was so famous in Nineveh that her statue was once sent from there to Egypt to help cure the Egyptian king of an illness. Assyrians offered food and precious objects to the gods. Priests tried to foretell the future by examining the innards of sacrificed animals and by observing and interpreting things in nature such as the weather and flights of birds.

Art and architecture. The earliest Assyrian art was similar to the art of Babylonia and of other nearby cultures. A separate style of Assyrian art developed between 1400 and 1000 B.C. Assyrian craftworkers made some of the finest cylinder seals ever produced in Mesopotamia. These seals were rolled over soft clay to seal documents and other objects.

The early Assyrians decorated their buildings with wallpaintings and with brightly colored bricks. Later, between 900 and 600 B.C., they decorated palace walls with carved stone slabs showing religious ceremonies or military victories. The wall carvings became the most familiar of all Assyrian artistic works. Some of the finest carvings, found at the palace of Ashurbanipal in Nineveh, show hunting scenes. Human figures in Assyrian art never display any emotion. But the carvings at Ashurbanipal's palace show vividly the ferocity and suffering of the hunted lions.

Assyrian relief carvings were skillfully done, but Assyrian sculptors never understood how to show distance and depth in their carvings. Except for the statues of human-headed bulls and lions that guarded the palaces, they made few good statues in the round.

Assyrians usually made their buildings of unbaked mud bricks. Some of the foundations and wall decorations were made of stone. All the buildings had flat

WORLD BOOK map

Location of the Assyrian Empire

roofs, and even the largest were only one story high. Some, however, had rooms with ceilings as high as 30 feet (9 meters). The magnificent palace courts, chambers, and hallways spread over several acres or hectares. Great temples and palaces as well as smaller buildings filled the cities of Assur, Nineveh, and Kalhu.

Assyrian craftworkers excelled in decorating small objects made of stone, metal, wood, and ivory. Some art objects were imported from Phoenicia and Egypt.

In the late 1980's, Iraqi archaeologists uncovered royal tombs at Kalhu containing exquisite examples of Assyrian gold work. The tombs held hundreds of beautifully crafted gold vessels and pieces of jewelry, including crowns, bracelets, necklaces, and earrings.

Government

The Assyrian king was known as "the great king, the legitimate king, the king of the world, king of Assyria, king of all the four corners of the earth, king of kings, prince without rival, who rules from the Upper Sea to the Lower Sea." The king served as supreme head of the Assyrian Empire and as chief priest of the god Ashur. He personally led the army in military campaigns to various parts of the empire. These campaigns brought in taxes and other payments. The king's oldest son and heir usually handled the administrative affairs of the country, and lived in the *Palace of Administration.*

Residents of some of the older cities, such as Assur and Nineveh, enjoyed special privileges, including low taxes and freedom from military service. Landlords had to pay taxes and provide young men from their estates to serve in the army. Beyond Assyria itself, the empire was divided into provinces. Each province was administered by a governor who was responsible to the central government.

Written records and sculptured reliefs indicate that the Assyrians treated conquered peoples cruelly. But sometimes the Assyrians only threatened to be cruel to frighten other peoples into surrendering. The Assyrians sometimes allowed conquered peoples to keep their own rulers. But if the people rebelled or refused to pay taxes, the Assyrians often destroyed their cities and sent the people to distant parts of the empire.

History

People began to settle in farming villages in Assyria about 8500 B.C. The villagers cultivated plants and domesticated sheep and goats. They traded goods with both nearby and distant towns and villages. As the population grew, villages in Assyria developed into small towns, and trade increased. Some Assyrians became wealthy and powerful, while others lived in simple homes with few possessions. By about 3000 B.C., many different peoples lived in Assyria.

From about 2000 to 1700 B.C., Assyrian traders established colonies in Anatolia (now part of Turkey) to acquire the silver and gold that were plentiful there. They traded tin and Babylonian cloth for the metals. In 1813 B.C., Shamshi-Adad, ruler of a desert people called the Amorites, took control of Assyria. He extended its powers and boundaries to western Syria, northern Mesopotamia, and the borders of Babylonia.

No records have been found of the next few hundred years of the history of Assyria. Historians believe that the country was ruled for part of the period by Mitanni, a kingdom in northern Syria. Records show that Assyria had again become independent by the mid-1300's B.C.

Assyria enjoyed brief periods of expansion in the 1200's and 1100's, before it began to build its empire in the 800's B.C. Shalmaneser III, who reigned from 858 to 824 B.C., gained control of the Mediterranean trade routes. Tiglath-pileser III, the king from 744 to 727 B.C., conquered large parts of Syria and Israel and became king of Babylonia. Esarhaddon, who held the throne from 680 to 669 B.C., added Egypt to the empire. Assyria declined after the mid-600's B.C., and Median and Babylonian attacks in 614 and 612 B.C. ended the empire.

Astaire, *uh STAIR,* **Fred** (1899-1987), an American dancer and actor, became a popular star of musical motion pictures. He was best known for his graceful, imaginative dancing and his lively portrayals of charming, sophisticated gentlemen.

Astaire, whose real name was Frederick Austerlitz, was born in Omaha, Nebraska. From 1916 to 1932, he and his sister, Adele Astaire, starred as a dance team in many Broadway musicals. Astaire made his movie debut in 1933 in *Dancing Lady.* Later that year, he teamed up with dancer Ginger Rogers in *Flying Down to Rio.* Their dancing delighted audiences,

Wide World

Fred Astaire

and Astaire and Rogers made nine more films together, including *Top Hat* (1935), *Swing Time* (1936), and *Shall We Dance?* (1937).

Astaire appeared in over 35 movies, including the musicals *Holiday Inn* (1942), *Easter Parade* (1948), *Royal Wedding* (1951), *The Band Wagon* (1953), and *Finian's Rainbow* (1968). He also played straight dramatic roles in such films as *On the Beach* (1959) and *The Towering Inferno* (1974). He died on June 22, 1987. Roger Ebert

Astana, *ah stah NAH* (pop. 300,000), is the capital of Kazakhstan. Astana serves as the railroad hub for a major grain- and livestock-producing region of Kazakhstan and is a center for food processing and industry. The city lies along the Ishim River on the plains of north-central Kazakhstan. For Astana's location, see **Kazakhstan** (map).

The city began in 1830 as a Russian military outpost. It soon grew into a town called Akmolinsk. In the 1950's, while Kazakhstan was a republic of the Soviet Union, the Soviet government chose the region around Akmolinsk as the site of the Virgin Lands project, an agricultural development project. In 1961, Akmolinsk was renamed Tselinograd, which means *Virgin Lands City*.

The Soviet Union broke up in 1991, and Kazakhstan became independent. The city adopted its Kazakh name, Aqmola (also spelled Akmola). In 1997, the country's capital was moved from Almaty to Aqmola, which is closer to the center of Kazakhstan. Aqmola was renamed Astana in 1998. *Astana* means *capital* in the Kazakh language. William Fierman

Astarte, *as TAHR tee,* is the Greek name for one of the most important goddesses of the ancient Middle East. Astarte was worshiped in Syria, Egypt, and the Phoenician colonies of the western Mediterranean.

The first mention of Astarte appeared about 1430 B.C. in Egyptian records that called her a war goddess. She was also a goddess of sexual love. The Greeks later identified her with Aphrodite, their goddess of love. Astarte was also related to the important Mesopotamian goddess Ishtar. An Egyptian myth about Astarte was found in a papyrus fragment that dates from approximately 1300 B.C. In this myth, Astarte apparently persuaded the Sea not to impose *tribute* (forced payments) on the deities of Egypt. The deities rewarded Astarte by accepting her into their circle. In the Bible, Astarte is called "Ashtoreth the goddess of the Sidonians" and Ashtaroth, the plural form of the name, is used with the meaning "pagan goddesses." Small clay figurines of nude females excavated in Palestine are often considered representations of Astarte. R. F. G. Sweet

Astatine, *AS tuh teen* or *AS tuh tihn,* is the heaviest member of the halogen family of chemical elements. It is extremely unstable, and all 30 of its isotopes undergo radioactive decay. Its most stable isotope has a half-life of 8 hours and an atomic weight of 210.

Astatine has the chemical symbol At and the atomic number 85. Its chemical properties resemble those of iodine. But astatine loses electrons in a chemical reaction more readily than does iodine. In addition, astatine is less likely than iodine to gain electrons (see **Iodine**).

Astatine was first prepared in 1940 by Dale R. Corson, K. R. MacKenzie, and Emilio Segrè at Berkeley, California. It was produced in a cyclotron by bombarding bismuth with high-energy alpha particles. Although small amounts of the element exist in uranium ores, almost all astatine is created artificially. Evan H. Appelman

Aster is the name of a large group of plants valued for their colorful flowers. Most asters are *perennials,* which means they live more than two years. Some are *annuals* that die after one growing season. More than 200 species of asters grow in North America, and lesser numbers are found in Europe, Asia, and South America. *Aster* is the Greek word for *star*.

The leaves of asters are positioned alternately along the stem. Each blossom is made up of two flowers—a small *disk flower* in the center surrounded by a petallike *ray flower*. The disk flowers range in color from white to dark purple. The ray flowers are most commonly white but also may be blue or purple. Most asters bloom late in summer. Some bloom until late fall.

WORLD BOOK illustration by Lorraine Epstein

The New England aster has purple petals.

The *New England aster* is a popular garden flower that blooms in the fall and has purple flowers. Its long narrow leaves grow on a hairy stem. Because these asters bloom at the time of the feast of Michaelmas, they are known as Michaelmas daisies in England.

Most asters are difficult to grow from seed. They can be broken into several pieces and transplanted in the spring. Asters thrive in almost any type of soil. The *China aster,* an annual, is grown from seed. James S. Miller

Scientific classification. Asters are in the composite family, Compositae. The scientific name for the New England aster is *A. novae-angliae*. The China aster is *Callistephus chinensis*.

See also Flower (picture: Garden perennials).

Asteroid is any of numerous small planetary bodies that revolve around the sun. Asteroids are also called minor planets or planetoids. Most of them are in the asteroid belt between the orbits of Mars and Jupiter. The belt contains more than 200 asteroids larger than 60 miles (100 kilometers) in diameter. Scientists estimate that there are more than 750,000 asteroids in the belt with diameters larger than $\frac{3}{5}$ mile (1 kilometer). There are millions of smaller asteroids. The average temperature of the surface of a typical asteroid is −100 °F (−73 °C).

Astronomers are not sure how the asteroids originated. According to the leading theory, however, most

known asteroids are the shattered remains of a smaller group of larger objects. These objects were left over from the time the planets formed. Elsewhere in the solar system, other such objects gathered together to form the planets and satellites.

Size. Asteroids vary greatly in size. The largest and first known asteroid, Ceres, was discovered in 1801. It is 580 miles (933 kilometers) in diameter. Ceres is believed to contain about $\frac{1}{3}$ of the total mass of all the asteroids. One of the smallest, discovered in 1991 and named 1991 BA, is only about 20 feet (6 meters) across.

Composition. Studies of an asteroid's reflected light as well as analyses of meteorites have provided information about the composition of asteroids. Astronomers classify asteroids into two broad groups based on their composition. One group of asteroids dominates the outer part of the belt. These asteroids are rich in carbon. Their composition has not changed much since the solar system formed. Asteroids in the second group, which are in the inner part of the belt, are rich in minerals. These asteroids formed from melted materials.

Measuring asteroids. Until the 1990's, astronomers could determine the size of an asteroid in only three ways. In the first method, they use telescopes to determine the asteroid's distance from the sun, the amount of the sunlight it reflects, and the amount of heat it gives off. The amount of sunlight or heat reaching the earth depends on the size of the asteroid and its distance from the sun. Therefore, calculations involving distance and either light or heat yield the size of the asteroid.

In the second method, astronomers use a telescope to measure an asteroid during an *occultation,* when the asteroid passes in front of a star and is silhouetted against it. The third technique involves the use of radio telescopes to produce images of an asteroid.

In 1991, scientists began to use a fourth method—close-range observation of asteroids by space probes. That year, the United States space probe Galileo took the first detailed photograph of an asteroid. This was Gaspra, an irregularly shaped object measuring about 12 by 7 $\frac{1}{2}$ by 7 miles (19 by 12 by 11 kilometers).

In 1996, the U.S. National Aeronautics and Space Administration (NASA) launched the Near Earth Asteroid Rendezvous (NEAR) probe. The probe flew within 753 miles (1,216 kilometers) of the asteroid Mathilde in 1997. In 1997, NEAR flew past the asteroid Eros at a distance of 2,378 miles (3,829 kilometers). NEAR went into orbit around Eros in February 2000. In March, NEAR was renamed Near Earth Asteroid Rendezvous-Shoemaker (NEAR Shoemaker) in honor of the American astronomer Eugene Shoemaker. In February 2001, NEAR Shoemaker became the first spacecraft to land on an asteroid.

In October 1998, NASA launched a probe called Deep Space 1. The probe flew within only about 16 miles (26 kilometers) of the asteroid Braille in July 1999.

NASA

The asteroid Ida is about 35 miles (55 kilometers) long. It is one of thousands of asteroids in the *asteroid belt,* a region between the orbits of Mars and Jupiter.

WORLD BOOK map

The Chicxulub Basin in Mexico's Yucatán Peninsula formed when an asteroid hit the earth about 65 million years ago. Debris from the impact may have led to the extinction of the dinosaurs.

Orbits. Most asteroids follow *elliptical* (oval-shaped) orbits in the asteroid belt. Groups of asteroids that follow the same orbit are called *Hirayama families,* named for Kiyotsugu Hirayama, the Japanese astronomer who first discovered them. Many asteroids follow orbits outside the belt. For example, a number of asteroids called Trojans follow the same orbit as does Jupiter. Three groups of asteroids—Atens, Amors, and Apollos—orbit in the inner solar system and are known as *near-Earth asteroids.* Some near-Earth asteroids cross the path of Mars, while others cross Earth's orbit.

Asteroid collisions. Many scientists believe that a near-Earth asteroid collided with Earth about 65 million years ago, triggering widespread environmental changes that led to the extinction of the dinosaurs. The asteroid created a huge circular depression called the Chicxulub (pronounced *CHEEK shoo loob*) Basin centered in Mexico's Yucatán Peninsula. The diameter of the basin is about 190 miles (300 kilometers).

In 1908, an object exploded about 6 miles (10 kilometers) above the Tunguska River area of Siberia. The object may have been a comet's nucleus or a large meteorite—sometimes referred to as a small asteroid. Debris from the explosion flattened forests and burned an area about 50 miles (80 kilometers) across.

The gravitational pull of Jupiter and other large planets causes asteroid orbits to change slowly. Orbital changes lead to collisions that create smaller asteroids and fragments, increasing the chance of more collisions. Some small fragments reach Earth's surface as *meteorites.* Marian E. Rudnyk

Asthma, *AZ muh,* is a chronic lung disease characterized by periods of breathlessness, wheezing, and coughing. People with asthma suffer from chronic inflammation of the *bronchi* (airways to the lungs). The inflamed airways react to irritation by swelling, constrict-

ing, and filling with mucus. These changes obstruct *airflow* (the ability to force air in and out of the lungs). An asthmatic person may feel short of breath or experience difficulty in breathing. Severe attacks may involve *spasms* (sudden constriction) of the airways, causing sufferers to gasp for air and feel that they are suffocating. These attacks require immediate medical attention and can cause death.

A variety of environmental or emotional stimuli, called triggers, may irritate the sensitive airways of asthma sufferers and cause an attack. Triggers include respiratory infections, pollen, mold spores, chemical irritants, tobacco smoke, animal dandruff, dust mites, exercise, or breathing cold air. An attack usually begins within minutes after exposure to a trigger and can last a few minutes, several hours, or even days.

Physicians diagnose asthma by studying the patient's history of symptoms, physical examination, and tests of lung function. Recurring episodes of breathlessness caused by one or more triggers usually indicate asthma. Physicians use a device called a *spirometer* to determine the amount of air patients can breathe out of their lungs. Another device called a *peak flow meter* measures airflow. People with asthma often have reduced airflow when exposed to triggering substances, or after vigorous exercise.

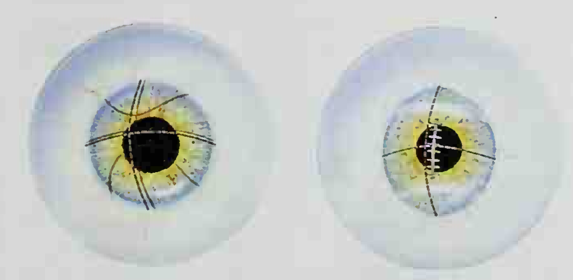
Asthma affects both children and adults. Some children with asthma experience fewer symptoms as they get older, while others develop more. Despite advances in the treatment of asthma, the incidence of the disease is increasing, especially among children living in cities.

Causes. Scientists are not certain what causes asthma or why it is becoming more common. Research shows that infants exposed to indoor air pollution, especially tobacco smoke, have a much higher risk of developing asthma than infants who are not exposed.

Asthma tends to run in families and is often accompanied by allergies. People with asthma, or members of their family, often have respiratory allergies, such as hay fever, or they are allergic to certain foods. Asthmatic persons and their family members also have a higher incidence of an allergy called atopic eczema that causes itchy red swellings on the skin. Researchers are working to discover genetic markers that can identify people at risk of developing asthma.

Treatment. There is currently no cure for asthma, but the disease can be controlled. Sudden attacks can be prevented by avoiding substances that trigger them. But it is not possible to avoid all asthma triggers all the time, so asthma sufferers usually require medication.

Medications are divided between those used for quick relief from sudden attacks, and others used for long-term control of symptoms. Quick-relief medicines are usually *bronchodilators,* drugs that decrease the constriction in the airways by relaxing small muscles in and around the lungs. These medicines are inhaled from small aerosol canisters at the onset of a sudden asthma attack. Long-term control medications include *corticosteroids,* which are *anti-inflammatories* (substances that reduce inflammation) that can be inhaled or taken orally.



Most people with asthma can lead normal, even active, lives. With proper treatment, people with asthma can participate in sports, even those that require intensive breathing, such as football, track and field, or swimming. Mark H. Moss and Robert F. Lemanske, Jr.

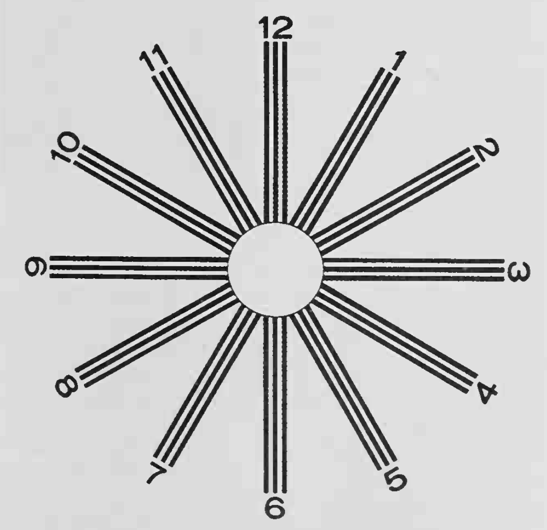
Astigmatism, *uh STIHG muh tihz uhm,* is a visual defect in which both nearby and distant objects appear blurred. It is usually found in both eyes. In most cases, astigmatism is caused by the shape of the cornea.



A normal cornea has a spherical shape, somewhat like a basketball cut in half. As light rays pass through a normal cornea, they are bent so they focus at a single point on the retina. In people with astigmatism, the cornea is shaped somewhat like a football cut in half lengthwise. The length and the width of the football-shaped cornea have unequal *curvatures* (degrees of curve), and the difference between these curves determines how much astigmatism the person has. Light rays entering an eye with astigmatism cannot focus on a single point on the retina. Instead, the rays meet at two points, one or neither of which is on the retina.

Many cases of astigmatism are present at birth. Some cases result from injury or disease. Astigmatism may develop or change as a person grows older, and it is often

Lisa Schonemen, University of Illinois at Chicago Eye Center

Astigmatism is usually caused by an abnormally shaped cornea. A normal cornea is shaped like a basketball and has equal curvatures, *left.* In a person with astigmatism, the cornea has unequal curvatures, like those of a football, *right.*

A practical test for astigmatism. The three parallel lines of each "spoke" in the "wheel" shown here are equally black. Cover one eye and hold the chart about 2 feet (60 centimeters) away. If all lines do not appear equally black, you may have astigmatism. Any eye condition should be checked by a doctor.

associated with nearsightedness or farsightedness. Mild cases of astigmatism may come and go.

The symptoms of astigmatism include blurred vision, double vision in one eye, eyestrain, fatigue, and headaches. People with astigmatism may squint in an effort to see clearly. Doctors treat it by prescribing glasses or contact lenses. In some cases, surgical or laser treatment of the cornea may restore a more spherical shape and reduce or eliminate astigmatism. Ronald A. Krefman

See also **Contact lens; Eye** (Astigmatism).

Astor, John Jacob (1763-1848), was a famous American businessman. He built a large fortune through his involvement in the fur trade and through his extensive real estate investments in New York. The investments increased in value over the years, and Astor's family became one of the wealthiest in the United States.

Astor was born in Walldorf, Germany, near Heidelberg. He came to New York City when he was 20 years old. He worked as a baker's boy and peddler and ran a music store before entering the fur trade in about 1787. He shipped furs overseas, often in his own vessels.

Astor's Pacific Fur Company established the trading post of Astoria, Oregon, in 1811, but lost it during the War of 1812. His fur companies won an almost complete monopoly of the trade in the United States. Astor invested his profits principally in Manhattan Island farmland, which became the heart of New York City. Astor retired from the fur trade in 1834. At his death, his estate was estimated at more than $20 million. John Elgin Foster

Astor, Lady (1879-1964), became the first woman to serve in the British Parliament. A Conservative, Astor was a witty champion of temperance and of the rights of women and children. Before World War II began in 1939, she became a prominent supporter of the policy of appeasement toward Nazi Germany (see **World War II** [The failure of appeasement]).

United Press Int.
Lady Astor

Astor was born Nancy Langhorne in Danville, Virginia. She went to England in 1903 and, in 1906, married Waldorf Astor, a great-great-grandson of the wealthy American businessman John Jacob Astor. Waldorf Astor served in the British House of Commons, where he represented the Sutton district of Plymouth. In 1919, he gave up his seat in the House, and Lady Astor was elected to replace him. Ten years later, after the election of 1929, Lady Astor tried unsuccessfully to form a women's party in the House under her leadership. She retired from the House in 1945. Keith Robbins

Astoria, *a STOHR ee uh* (pop. 9,813), is a historic seaport at the mouth of the Columbia River in the northwest corner of Oregon. It is the seat of Clatsop County. For location, see **Oregon** (political map). The chief industries in the area are fishing, fish packing, wood products milling, and shipping.

The city gets its name from a fur-trading post established in 1811 by a party sent out by John Jacob Astor. It was the first American settlement west of the Rocky Mountains. The post was located near the site of Fort Clatsop, where the Lewis and Clark Expedition spent the winter of 1805-1806.

The Clatsop County Historical Society Museum and the Columbia River Maritime Museum are located in Astoria. The city has a council-manager government.
Gordon B. Dodds

Astrolabe, *AS truh layb,* is an instrument used by early astronomers and navigators to measure the angles of celestial bodies above the horizon. It consists of a metal disk mounted on a circular frame. The astrolabe is suspended so that it remains vertical. The disk has sights for observing a star. The frame has a set of marks for measuring the star's elevation. The astrolabe was replaced by the sextant and other more accurate instruments. See also **Exploration** (picture); **Navigation** (History); **Sextant.**
Raymond E. White

Astrology, *uh STRAHL uh jee,* is the study of how the sun, moon, planets, and stars are supposedly related to life and events on the earth. It is based on the belief that the heavenly bodies form patterns that can reveal a person's character or future.

Many people throughout the world believe in astrology. They base important decisions on the advice of an *astrologer* (a person who tells fortunes by studying the stars). Other people say there is no scientific basis for astrology, and they consider it a form of entertainment.

Astrology differs from astronomy. Astrology developed from a set of principles that originated more than 4,000 years ago. At that time, astronomy was also based on the same principles. But during the 1500's and 1600's, several astronomers, including Nicolaus Copernicus of Poland and Tycho Brahe of Denmark, made discoveries about the heavenly bodies that conflicted with the principles of astrology. As a result, astrology and astronomy became widely different in their methods and purpose. Today, astrologers observe the heavenly bodies to understand things that happen on the earth. Astronomers seek scientific knowledge about objects in space.

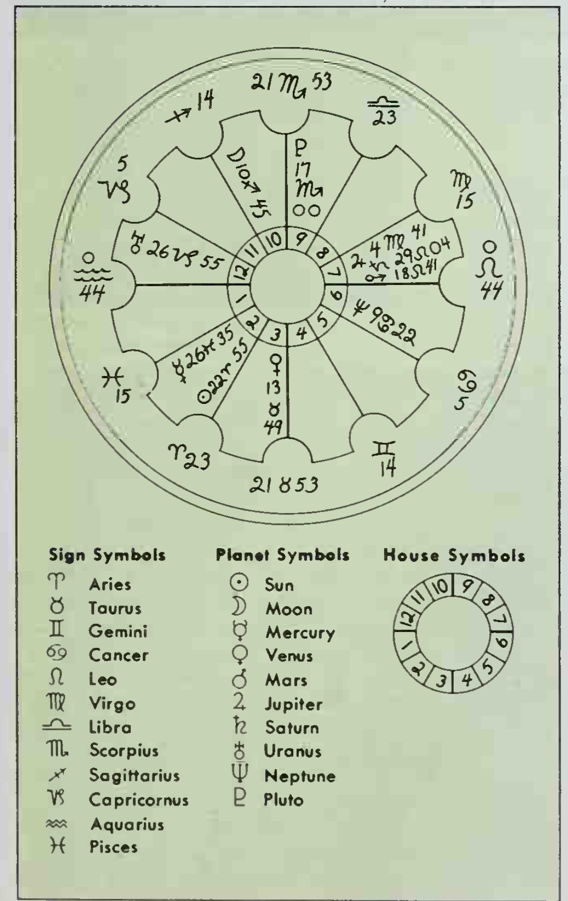
Principles of astrology

The basic principle of astrology is that the heavenly bodies influence what happens on the earth. Astrologers learn about this influence by *casting* (drawing) a circular chart called a *horoscope* or *birth chart.* A horoscope shows the position of the planets in relation to both the earth and the stars at a certain time. In most cases, it shows the position of these bodies at the time of a person's birth. See **Horoscope.**

The system used by astrologers to cast a horoscope is based on a special view of the universe. This view involves four elements: (1) the earth, (2) the planets, (3) the zodiac, and (4) the houses.

The earth. In casting a horoscope, astrologers place the earth at the center of the solar system. Therefore, all heavenly bodies revolve around the earth rather than around the sun. Astrologers use this arrangement to determine the positions of the heavenly bodies in relation to the earth. They believe that the study of the positions of the heavenly bodies can reveal a person's character and future.

The planets. In astrology, the moon and the sun are considered planets, along with Jupiter, Mars, Mercury, Neptune, Pluto, Saturn, Uranus, and Venus. Each planet supposedly represents a force that affects people in a certain way. Astrologers believe the planets influence a person more than do any other heavenly bodies.



The zodiac is a band of stars that appears to encircle the earth. It is divided into 12 equal parts called *signs.* Each sign of the zodiac has certain characteristics, which are determined by a particular planet and other factors. Astrologers believe the signs determine how the planets affect a person's character. See **Zodiac**; and the articles on the signs of the zodiac, such as **Aries**.

The houses. Like the zodiac, the earth's surface is divided into 12 parts. Each of these parts, called *houses,* represents certain characteristics of an individual's life. Astrologers believe the houses determine how the planets and the signs influence a person's daily life. See **House** (in astrology).

A horoscope and astrological symbols

Astrologers study charts called *horoscopes* or *birth charts* to foretell the future. A person's chart shows the position of the planets in relation to the earth and stars at his or her birth. Astrologers believe that these patterns reveal the person's character and future. The chart shown here is the horoscope of President Thomas Jefferson.

WORLD BOOK illustration adapted from *Horoscopes of the U.S. Presidents* by Doris Chase Doane

History

Astrology began sometime before 2000 B.C. in Babylonia (now southeastern Iraq). Astrologers of that time knew of five planets—Jupiter, Mars, Mercury, Saturn, and Venus. They believed that the sun, moon, and planets sent out different forces, which had certain characteristics. For example, one of the planets—now known as Mars—appeared to be red. Astrologers linked it with anger, aggression, and war.

The 12-sign zodiac was probably first used in the Middle East sometime during the 1000's B.C. Astrologers gradually developed a system that linked seasonal changes with specific groups of stars called *constellations* (see **Constellation**). At that time, for example, heavy rainfall occurred in the Middle East when the sun was in a certain constellation. As a result, astrologers named the constellation Aquarius, the water bearer.

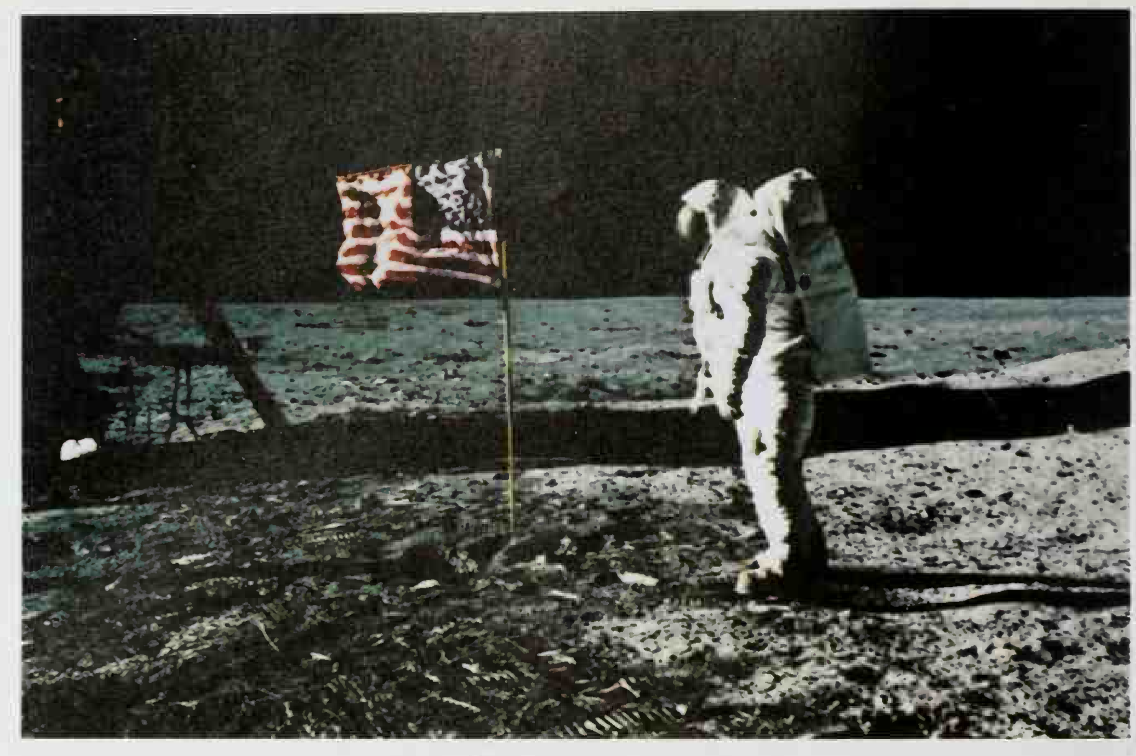
At first, astrologers studied the heavenly bodies in making general predictions about the future. But between 600 B.C. and 200 B.C., they developed the system of casting individual horoscopes. The ancient Greeks and Romans practiced astrology and greatly influenced its development. The Roman names for the planets and the signs of the zodiac are still used today.

Interest in astrology declined in Europe with the coming of Christianity as people sought guidance from religious leaders rather than from astrologers. Astrology regained popularity during the A.D. 1100's. By the 1600's, it was particularly strong in England. Several astrological almanacs were published, and many other books either defended or attacked astrology. The number of followers of astrology fell in England during the 1700's, but the subject's popularity returned again in the early 1800's. By the late 1800's and early 1900's, interest in astrology had spread to many other nations.

Newspapers in England began publishing horoscope columns during the 1930's. Such columns soon appeared in newspapers throughout the world, and people became increasingly interested in astrology. Today, astrology is followed more widely than ever before.

Astrology today

Many people believe astrology is simply a superstition, and scientists declare that its whole basis is unscientific. Scientists point out that the earth's position has changed in space since ancient times. As a result, the dates astrologers associate with the signs of the zodiac no longer match the positions of the constellations for which they were named.



Some people who believe in astrology support it in terms of magnetic fields, solar storms, and other natural occurrences. Others, though they also believe in astrology, claim that it cannot be supported scientifically. They consider it a set of powerful symbols that can provide a deep understanding of human beings. They defend astrology by pointing out that, in many cases, it works.

Astronaut

Astronaut is a person who pilots a spacecraft or works in space, particularly in the space program of the United States. In Russia and the other former republics of the Soviet Union, such men and women are called *cosmonauts.* The cosmonaut program was a project of the Soviet Union until that country broke up in 1991. Russia then took over the program. China also has an astronaut-training program and hopes to send its first astronauts into space in the early 2000's.

Astronauts and cosmonauts operate spacecraft and space stations, launch and recapture satellites, and conduct scientific experiments. The word *astronaut* comes from Greek words that mean *sailor among the stars. Cosmonaut* means *sailor of the universe.*

Most astronauts work for the National Aeronautics and Space Administration (NASA). They live and train at the Lyndon B. Johnson Space Center in Houston. Astronauts travel into space aboard space shuttles.

NASA selects two kinds of astronauts for space flights—*pilot astronauts* and *mission specialist astronauts.* Pilot astronauts command and pilot shuttles. Most pilot astronauts are test pilots from the United States Air Force, Navy, or Marine Corps. They are paid according to their military rank.

Mission specialists work with pilots to maintain spacecraft and the equipment aboard. They also conduct experiments and launch satellites. In addition, they perform spacewalks to work outside the spacecraft.

Mission specialists may be engineers, scientists, or physicians who have extensive research experience. Those who are in the armed forces are paid according to their rank. The civilians receive salaries based on an equivalent rank in the *civil service system.* This system includes almost all the federal government's civilian employees who are appointed rather than elected.

A third kind of astronaut is called a *payload specialist.* This kind of astronaut carries out scientific experiments involving the *payload* (cargo) on the spacecraft. Most payload specialists are scientists who work for the owner of the payload. They must be approved by NASA.

The term *astronaut* also has a meaning that is not connected with NASA activities. In the 1960's, the United States Department of Defense awarded the rating of *astronaut* to military and civilian pilots who flew aircraft higher than 50 miles (80 kilometers). Seven test pilots received this rating for flights in the X-15 rocket plane. Flights of the X-15 ended in 1968.

Cosmonauts train at the Yuri Gagarin Russian State Scientific-Research Test Center of Cosmonauts Training, located in Starry Town, also known as Star City, near Moscow. They travel into space aboard vehicles called Soyuz. Unlike space shuttles, these vehicles are not reusable. Crews lift off from the Baykonur Cosmodrome, located near the Aral Sea in south-central Kazakhstan.

James Oberg, the contributor of this article, is a space-flight engineer, author, and lecturer.

Landings take place in remote, flat areas of Kazakhstan.

A Soyuz carries two or three specialized cosmonauts. The commander is almost always a military jet pilot, and the flight engineer is almost always a civilian. The flight engineer is usually a member of the staff of the design bureau responsible for the craft. On about half the Soyuz flights, a third cosmonaut, usually called the cosmonaut researcher, is aboard. This person can be a non-Russian "guest cosmonaut" or a Russian physician.

Cosmonauts began making guest flights aboard space shuttles in 1994, and astronauts began visiting Russia's Mir space station in 1995. Both astronauts and cosmonauts helped build, and then worked aboard, the International Space Station.

Achievements in space

On April 12, 1961, Yuri A. Gagarin of the Soviet Union became the first person to travel in space. He orbited the earth once in a Vostok capsule. *Vostok* is Russian for *east*. Gagarin's flight lasted 1 hour 48 minutes. Twenty-three days later, on May 5, Alan B. Shepard, Jr., became the first American space traveler. He made a 15-minute flight in a Mercury capsule but did not go into orbit. John H. Glenn, Jr., the first American in orbit, circled the earth three times on Feb. 20, 1962.

The first woman in space, cosmonaut Valentina Tereshkova, was in space for 3 days in 1963. Twenty years later, astronaut Sally K. Ride became the first American woman in space. In June 1983, Ride orbited the earth with four other crew members on a six-day mission aboard the space shuttle Challenger.

In 1964, the Soviet Union placed the first three-person spacecraft in orbit. This design was called Voskhod, which is Russian for *sunrise*. In 1965 and 1966, the United States conducted a series of 10 two-person flights in Gemini spacecraft. During those flights, the astronauts practiced maneuvering their craft and joining it to other orbiting space vehicles.

On March 18, 1965, cosmonaut Alexei A. Leonov became the first person to step outside a spacecraft and float freely in space. Less than three months later, on June 3, astronaut Edward H. White II made the first space walk for the United States.

In 1967, cosmonauts began flying the Soyuz series of spacecraft. These are three-seat vehicles, but the first crewed flight carried only one cosmonaut, and other early flights carried two. The Soviet Union also tested spacecraft to send cosmonauts to the moon and land them there. After many failures, however, the Soviets canceled their moon-trip projects.

Space flights of the Apollo program, the U.S. project to land astronauts on the moon, began in October 1968.

Sovfoto

Yuri A. Gagarin of the Soviet Union was the first person in space. He rocketed into orbit on April 12, 1961, in the Vostok 1 spacecraft. Gagarin made one orbit of the earth.

Wide World

John H. Glenn, Jr., America's first orbiting astronaut, circled the earth three times on Feb. 20, 1962. Glenn took control of his space capsule, Friendship 7, after its automatic controls failed.

Astronauts on a space shuttle mission work in a pressurized laboratory called Spacelab. The shuttle carries Spacelab within its cargo bay, and a tunnel connects the laboratory to the crew compartment. Each Spacelab mission focuses on research in a particular area of science or technology, such as life sciences or materials processing.

On December 24 and 25 of that year, Frank Borman, James A. Lovell, Jr., and William A. Anders orbited the moon 10 times in 20 hours. In doing so, they became the first people to orbit a celestial body other than the earth.

On July 20, 1969, astronauts Neil A. Armstrong and Buzz Aldrin became the first people to set foot on the moon. They landed the Apollo 11 lunar module, called the Eagle, and performed scientific experiments and collected rock samples. Other astronauts made five more moon landings from 1969 to 1972.

In June 1971, cosmonauts established the first space station, Salyut 1. In 1973, the United States sent up a team of astronauts to operate its first space station, Skylab. Astronauts Charles Conrad, Jr., Joseph P. Kerwin, and Paul J. Weitz lived in Skylab for almost a month.

In 1975, the United States and the Soviet Union undertook their first joint space mission, the Apollo-Soyuz Test Project. On July 17, an Apollo spacecraft docked with a Soyuz craft. The Apollo craft carried astronauts Thomas P. Stafford, Vance D. Brand, and Donald K. Slayton. Aboard the Soyuz were cosmonauts Alexei A. Leonov and Valery N. Kubasov. For two days, the five spacefarers conducted experiments in the docked craft.

On April 12, 1981, the United States launched the space shuttle Columbia, the first reusable spacecraft to carry a crew. Astronauts John W. Young and Robert L. Crippen orbited the earth more than 36 times during a flight lasting about 2 days 6 hours. On Nov. 28, 1983, Columbia carried the first European-built research laboratory, called Spacelab, into space.

Cosmonaut Valery Polyakov completed a record 438 days in space on March 22, 1995. Polyakov spent this time aboard Mir. His mission helped scientists study how extended periods of weightlessness affect the human body.

Astronauts first recovered, repaired, and relaunched a disabled satellite in April 1984. Traveling aboard Challenger, they used a Canadian-made robot arm to capture the satellite. In May 1992, astronauts aboard the shuttle Endeavour captured a satellite using only their gloved hands. They then attached a special tool to the satellite so that a robot arm could hold it. In December 1993, astronauts aboard Endeavour repaired the Hubble Space Telescope. They installed a device that made up for a defect in the telescope's main mirror.

Accidents in space

Space travel is risky, and a number of astronauts and cosmonauts have lost their lives in training or on space flights. The first fatality in a space program occurred on March 23, 1961. Valentin V. Bondarenko, a Soviet cosmonaut trainee, died in a fire in a pressure chamber.

During a ground test on Jan. 27, 1967, an Apollo spacecraft caught fire, killing the three astronauts inside. The astronauts—Virgil I. Grissom, Edward H. White II, and Roger B. Chaffee—had been scheduled to fly the first Apollo spacecraft.

On April 24, 1967, cosmonaut Vladimir Komarov became the first person to die on a space flight. Komarov's flight was the first in which a Soyuz vehicle carried a cosmonaut into space. When Komarov tried to land the vehicle, its parachutes failed to open properly. Komarov died when the Soyuz crashed to earth.

The first mission in which people occupied a space station also ended in disaster. In June 1971, Georgi T. Dobrovolsky, Victor I. Patsayev, and Vladislav N. Volkov boarded the experimental station Salyut 1 from their Soyuz 11 spacecraft. During their 23-day mission, they conducted medical examinations of one another and carried out scientific studies. On the return flight, all three cosmonauts died because of a sudden loss of cabin pressure in the Soyuz.

On Jan. 28, 1986, Challenger broke apart shortly after launch. All seven crew members were killed. They included Christa McAuliffe, a teacher, who was aboard as part of a program to make the experience of space flight

Important astronaut and cosmonaut "firsts"

Date	Name	Achievement
April 12, 1961	Cosmonaut Yuri A. Gagarin	First person in Earth orbit
May 5, 1961	Astronaut Alan B. Shepard, Jr.	First American in space
Feb. 20, 1962	Astronaut John H. Glenn, Jr.	First American in Earth orbit
June 16, 1963	Cosmonaut Valentina Tereshkova	First woman in space
March 18, 1965	Cosmonaut Alexei A. Leonov	First person to "walk" in space
July 20, 1969	Astronauts Neil A. Armstrong and Buzz Aldrin	First crew to land on the moon
June 7, 1971	Cosmonauts Georgi T. Dobrovolsky, Victor I. Patsayev, and Vladislav N. Volkov	First crew of an orbiting space station
May 25, 1973	Astronauts Charles Conrad, Jr., Joseph P. Kerwin, and Paul J. Weitz	First crew of a U.S. space station
March 2, 1978	Cosmonaut Vladimir Remek (Czechoslovak)	First non-Soviet cosmonaut
July 23, 1980	Cosmonaut Pham Tuan (Vietnamese)	First Asian in space
April 12, 1981	Astronauts John W. Young and Robert L. Crippen	First space shuttle flight
June 18, 1983	Astronaut Sally K. Ride	First American woman in space
Aug. 30, 1983	Astronaut Guion S. Bluford, Jr.	First African American in space
Oct. 5, 1984	Astronaut Marc Garneau	First Canadian in space
Jan. 24, 1985	Astronaut Ellison Shoji Onizuka	First Asian American in space
Jan. 12, 1986	Astronaut Franklin R. Chang-Diaz	First Hispanic American in space
Jan. 22, 1992	Astronaut Roberta Bondar	First Canadian woman in space
Sept. 12, 1992	Astronaut Mae C. Jemison	First African American woman in space
April 8, 1993	Astronaut Ellen Ochoa	First Hispanic American woman in space
March 22, 1995	Cosmonaut Valery Polyakov	Completed record 438 days in space
Sept. 26, 1996	Astronaut Shannon Wells Lucid	Completed 188 days in space, a record for women and Americans
July 23-28, 1999	Astronaut Eileen M. Collins	First woman to command a shuttle
June 19, 2002	Astronauts Daniel Bursch and Carl Walz	Completed 196 days in space, a new record for Americans

better known to the public. After the Challenger disaster, NASA canceled this program and suspended all shuttle flights. Astronauts returned to space on Sept. 29, 1988, aboard the shuttle Discovery.

Selecting the astronauts

NASA accepts applications for pilot astronauts and mission specialist astronauts on a continuing basis. A selection board normally picks a group of about 15 to 25 candidates every two years. An applicant must be a U.S. citizen and must hold a bachelor's degree or higher in engineering, a biological science, a physical science, or mathematics. There is no age limit, but every candidate must pass the NASA space flight physical examination.

Pilot astronaut candidates must have flown for 1,000 hours as a command pilot in high-performance jet aircraft. They must be between 5 feet 4 inches and 6 feet 4 inches (163 and 193 centimeters) tall. Candidates for mission specialist do not need flight experience, but they must have at least three years of related professional experience. They must be between 5 feet and 6 feet 4 inches (152 and 193 centimeters) tall.

A look at the astronauts

Since 1959, more than 250 astronauts have flown in space. NASA chose seven test pilots as the first group of astronauts and introduced them to the public on April 9, 1959. The group consisted of Air Force officers L. Gordon Cooper, Virgil I. Grissom, and Donald K. Slayton; Navy pilots M. Scott Carpenter, Walter M. Schirra, Jr., and Alan B. Shepard, Jr.; and Marine Corps pilot John H. Glenn, Jr. In the 1960's, NASA selected an additional 49 experienced jet pilots. From 1965 to 1967, NASA picked 17 scientist astronauts.

In 1978, NASA announced the selection of astronauts for upcoming flights of the space shuttle. In this group were 15 pilot astronauts and the first 20 mission specialists. Among the mission specialists were the first six women selected to become astronauts. All six held doctor's degrees. They were physician Anna L. Fisher, biochemist Shannon Wells Lucid, electrical engineer Judith A. Resnik, physicist Sally K. Ride, physician Margaret R. Seddon, and geologist Kathryn D. Sullivan. In 1990, NASA chose the first woman to become a pilot astronaut, Eileen Marie Collins.

In 1983, Canada selected six of its citizens to receive training for NASA missions. The next year, Marc Garneau, a commander in the Canadian Navy, flew aboard Challenger. He thereby became the first Canadian astronaut to travel in space. NASA has also flown payload specialists from Belgium, France, Germany, Italy, Japan, Mexico, the Netherlands, Saudi Arabia, Spain, Switzerland, and Ukraine, and cosmonauts from Russia.

In 1985, Senator Edwin J. (Jake) Garn of Utah became the first elected official to fly in space. He was chairman of the Senate committee that had oversight responsibilities for the NASA budget. Garn flew aboard Discovery. The next year, Congressman C. William Nelson of Florida flew aboard Columbia. In 1998, John Glenn, then a U.S. senator, returned to space aboard Discovery. He was 77 years old at the time of the flight, making him the oldest person ever to travel in space.

Training the astronauts

Candidates for pilot and mission specialist undergo one year of general training at Johnson Space Center. After successfully completing this training, they become astronauts. The training involves two major phases: (1) a general phase, involving classroom work, flight training, and survival training; and then (2) more specific basic mission training and advanced mission training.

Classroom work. NASA brings in instructors from its research centers and from universities to teach aerodynamics, physics, physiology, computer science, and other subjects. Experienced astronauts lecture on such topics as how to communicate with astronauts in space. Other NASA personnel discuss the people, equipment, and funding that make space flight possible.

Mercury and Gemini astronauts took courses in rocket engines, flight mechanics, and navigation. In addition to those subjects, Apollo astronauts studied the geology of the moon. They also traveled to Hawaii, Iceland, Alaska, and other places to study volcanic rocks similar to those on the moon. Skylab crews took classes in astronomy, geology, and life sciences to enable them to perform experiments and make observations.

Flight training takes place in T-38 jet aircraft. Once mission specialist candidates learn to operate the aircraft , they fly about 4 hours per month. Pilot candidates must fly 15 hours. Pilots are also trained on a special airplane called *Shuttle Training Aircraft* (STA). These airplanes perform as a space shuttle does during landing.

Astronauts are weightless in space, and so they must anchor themselves with straps and other devices to keep from floating about. Aboard the *Skylab* space station, *shown here,* Gerald P. Carr appears to be supporting a weightless Edward Gibson with one finger.

Survival training teaches candidates how to survive after an unplanned landing in water or in a forest. Before shuttle flights, returning spacecraft landed in the ocean. The space shuttle lands on a runway, but astronaut candidates prepare for emergency bailout over water from shuttles and T-38's. For example, they are towed through the water in a parachute harness to simulate being dragged by a parachute in a wind. In addition, candidates practice survival training in the wilderness.

Basic mission training involves the study of cockpit layout and flight-control systems. Candidates also prepare for the actual conditions of space flight.

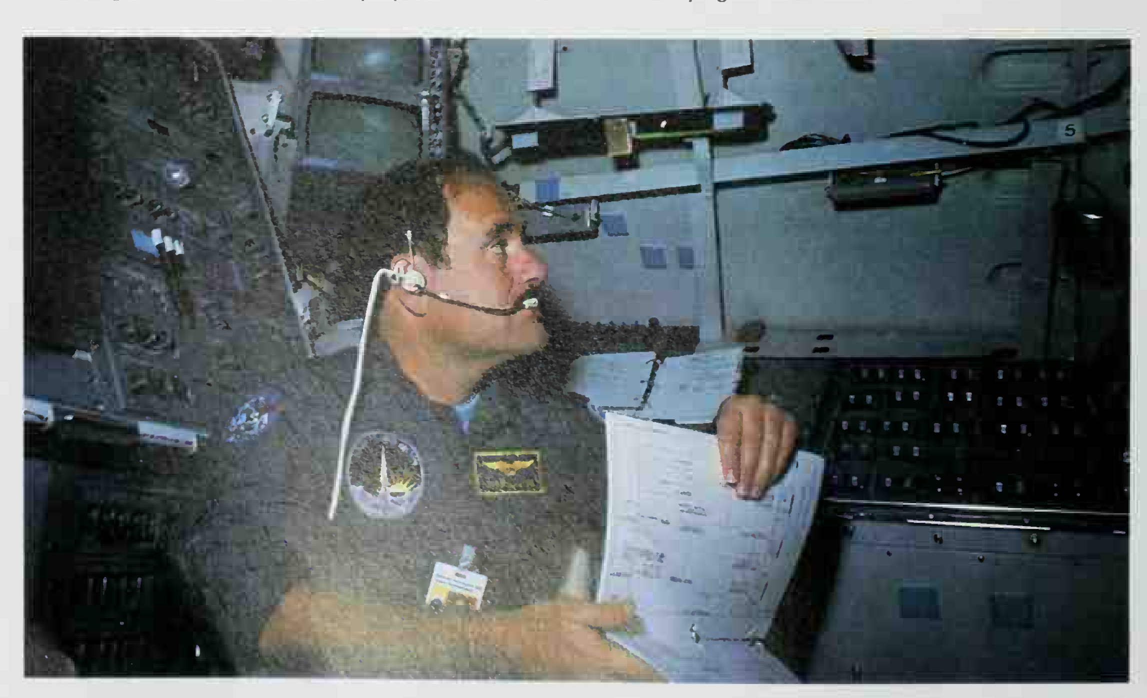
Candidates for pilot and mission specialist train for weightlessness in two ways. They ride in large airplanes that fly through a series of arcing climbs and dives. For about 30 seconds during each arc, they float weightlessly in the padded body of the aircraft. Floating in water also *simulates* (reproduces conditions of) weightlessness. The tanks used for training purposes are known as the *Weightless Environmental Training Facility* (WETF) and the *Neutral Buoyancy Laboratory* (NBL).

After successful completion of the training program, new astronauts continue to develop their skill while they wait for crew assignments. Some become experts in several support or operational areas.

Advanced mission training. Once assigned to a crew, astronauts spend most of their time training in simulators. Shuttle astronauts train in the *Shuttle Mission Simulator* (SMS). This device can reproduce the events of an entire mission. Crew members spend as many as eight hours a day in the simulator. Instructors continually give the crew problems to solve to prepare them for emergency situations.

Training in simulators is valuable preparation for what they may later face on actual flights. For example, in 1970, the Apollo 13 astronauts used the oxygen and power supply of their lunar module to return home safely after an explosion damaged their main spacecraft. This operation was less difficult to carry out because the crew was very knowledgeable about all systems on board.

Astronauts also train in *mock-ups*—that is, full-sized models of the spacecraft. The astronauts store items, prepare foods, and check equipment in the mock-ups. They also practice entering and leaving the spacecraft.



Advanced training prepares astronauts for tasks that are not part of all missions. For example, astronauts involved in the 1975 Apollo-Soyuz project and the visits to Mir in 1995 learned the Russian language. They also studied the operation of Russian space vehicles.

Astronauts who work in the Spacelab practice operating special equipment and instruments needed to conduct experiments. Astronauts preparing for spacewalks receive extra training in the WETF and the NBL.They also train with virtual reality systems.

Astronauts on the ground

Astronauts taking part in a space mission work on the ground as well as in space. Those on the ground relay information and instructions from flight controllers, engineers, and scientists to the crew. If problems develop, other astronauts help engineers find solutions.

Astronauts have helped change the design of spacecraft and their operating systems. For example, Mercury astronauts insisted on a window in the capsule and a hatch that opened from the inside. Also, skill displayed by the astronauts led designers to give them more control over flying the craft. Shuttle astronauts worked on

Training in a simulator, an astronaut learns about the instruments and controls of a space shuttle. When an astronaut operates the controls, the simulator shows how an actual shuttle would react.

the location of instruments and the modification of space suits. They also helped develop special equipment, such as satellite repair tools.

The cosmonauts

Since April 1961, about 100 cosmonauts have flown in space. Most of them have been from the Soviet Union and, since 1991, Russia. The first cosmonauts were military pilots. Most were in their middle 20's, and many were sent to college after returning from space. Since 1964, crews of cosmonauts could include civilian engineers and physicians.

The first cosmonauts spent less than two years in training. The original training program involved constant athletic activity. It included swimming, running, cycling, and parachute jumping over land and water. The U.S. program did not require such activities, but the astronauts were expected to get into good physical condition on their own.

The early Soviet program also included training in heat chambers and an isolation cell. They also sat in a spinning, swinging chair that was designed to test for motion sickness.

As the Soviets became more experienced in space travel, they learned that training did not need to be so demanding. They eliminated the heat and isolation chambers, and required less parachute jumping. In addition, motion sickness training became easier. Today, cosmonauts spend most of their time studying complex spacecraft systems and working in simulators. They now spend several years preparing for space flight.

The Soviet Union and Russia have sent guest cosmonauts into space since 1978. These cosmonauts' home countries included Afghanistan, Austria, Bulgaria, Cuba, Czechoslovakia (now the Czech Republic and Slovakia), France, the former East Germany, Germany, Hungary, India, Japan, Kazakhstan, Mongolia, Poland, Romania, Slovakia, Syria, the United Kingdom, Vietnam, the United States, and the former West Germany. Stars fill the sky in the large photograph, which shows what can be seen with the unaided eye. The familiar Big Dipper tilts downward toward the mountain at the left. The inset photo, taken by the powerful Hubble Space Telescope, shows how much more astronomers can see with telescopes. It reveals galaxies filling a tiny speck of sky near the Dipper's "handle."

NASA

Astronomy

Astronomy is the study of the universe and the objects in it. Astronomers observe the sky with telescopes that gather not only visible light but also invisible forms of energy, such as radio waves. They investigate nearby bodies, such as the sun, planets, and comets, as well as distant galaxies and other faraway objects. They also study the structure of space and the past and future of the universe.

Astronomers seek answers to such questions as: How did the universe begin? What processes release energy deep inside stars? How does one star "steal" matter from another? How do storms as big as Earth arise on Jupiter and last for hundreds of years?

To answer such questions, astronomers must study several subjects besides astronomy. Almost all astronomers are also astrophysicists because the use of physics is essential to most branches of astronomy. For example, some parts of *cosmology,* the study of the structure of the universe, require an understanding of the physics of elementary particles, such as the bits of matter called *quarks* that make up protons and neutrons. Astronomers use chemistry to analyze the dusty, gaseous matter between the stars. Specialists in the structure of planets use geology.

Astronomy is an ancient science. Like today's researchers, ancient scholars based their ideas of the uni-

The contributor of this article is Jay M. Pasachoff, Field Memorial Professor of Astronomy and Director of the Hopkins Observatory at Williams College.

verse on what they observed and measured and on their understanding of why objects move as they do. However, the ancients developed some incorrect ideas about the relationships between Earth and the objects they saw in the heavens. One reason for their errors was that they did not understand the laws of motion. For example, they did not know that a force—which we know as gravitation—controls the movements of the planets. Another reason was that their measurements did not reveal the movements of the planets in sufficient detail.

The ancients noted that the positions of the sun, moon, and planets change from night to night. We know that these movements are a result of the revolution of the moon about Earth and the revolution of Earth and the other planets about the sun. The ancients, however, concluded that the sun, moon, and planets orbit a motionless Earth. In many places, religious teachings supported this conclusion until the 1600's.

Although ancient people misinterpreted much of what they saw in the heavens, they put their knowledge of astronomy to practical use. Farmers in Egypt planted their crops each year when certain stars first became visible before dawn. Many civilizations used the stars as navigational aids. For example, the Polynesians used the positions of the stars to guide them as they sailed from island to island over thousands of miles or kilometers of the Pacific Ocean.

Observing the sky

If you look at the night sky without a telescope or a pair of binoculars, you will see what the ancients saw. If the night is clear and you are far from city lights, you will see about 3,000 stars. Stretching across the sky will be a splotchy band of bright and dark areas called the Milky Way. In addition, a few fuzzy spots will be visible.

Ancient people in the Western world noticed that certain stars are arranged in patterns shaped somewhat like human beings, animals, or common objects. Many ancient civilizations associated such patterns, called *constellations,* with mythology. Many names of constellations have come to us from Greek myths. In one myth, Artemis, goddess of hunting, was greatly saddened by the death of a human hunter named Orion. In her sorrow, she placed Orion in the sky as a constellation.

How the stars move. If you map the location of several stars for a few hours, you will observe a regular motion. The stars move relative to Earth because of Earth's rotation about its own axis. All stars move in circles around a point in the sky known as a *celestial pole.* Stars rotate counterclockwise around the celestial north pole and clockwise around the celestial south pole. Stars that are far from the pole rise from below the horizon in the east, move upward, and then set in the west.

One bright star, Polaris, is so close to the celestial north pole that it moves very little. Because of its location, Polaris is also known as the North Star. There is no "South Star," but the constellation Octans (Octant) is close to the celestial south pole.

The sun, like the other stars, rises in the east and sets in the west. But the sun also moves eastward relative to the other stars about 1° each day. By noting which stars are visible above the horizon just before sunrise and just after sunset, people have mapped the path of the sun among the stars for thousands of years. This path is known as the *ecliptic,* and the band of constellations near this path is called the *zodiac.*

How the planets move. With the unaided eye, you can see the planets Mercury, Venus, Mars, Jupiter, and Saturn. The planets move every night from east to west along the zodiac. In addition, their position in the zodiac changes from night to night. That is, when viewed at the same time on successive nights, the planets move relative to the background stars. Most of the year, they move from west to east.

The planets also have a motion that differs from that of any other celestial object. In their night-to-night movement relative to the stars, they slow down, stop, and then move westward in what is known as *retrograde motion.* They then slow down again, stop, and resume their eastward motion.

How the moon moves. The moon is the brightest and most easily seen object in the night sky. As a result, the most familiar observation is of the moon's *phases,* such as the full moon, half moon, and crescent. The moon moves from east to west as it rises and sets. From night to night, the moon moves eastward about 13° relative to the stars, rising almost an hour later each night.

Earth-centered theories. Ancient scholars produced elaborate schemes to account for the observed movements of the stars, sun, moon, and planets. In the 300's B.C., the Greek philosopher Aristotle developed a system of 56 spheres, all with the same center. The innermost sphere, which did not move, was Earth. Around Earth were 55 transparent, rotating spherical shells. The outermost shell carried the stars, believed to be merely points of light. Other shells carried the sun, moon, and planets. These shells rotated inside other shells that rotated within still other shells in ways that accounted for almost all the observed movements.

During the A.D. 100's, Ptolemy, a Greek astronomer who lived in Alexandria, Egypt, offered an explanation that better accounted for retrograde motion. Ptolemy said that the planets moved in small circles called *epicycles.* The epicycles moved in large circles called *deferents.* Earth was near the center of all the deferents.

Sun-centered theories. By the early 1500's, the Polish astronomer Nicolaus Copernicus had developed a theory in which the sun was at the center of the universe. This theory correctly explained retrograde motion as the changing view of the planets as seen from a moving Earth. The theory also correctly explained the east-to-west movement of the sun and stars across the sky. This movement is due to the west-to-east rotation of Earth about its own axis, rather than an actual motion of the sun and stars.

Several decades later, the Danish astronomer Tycho Brahe built gigantic instruments that he used to make precise measurements of planetary movements. German mathematician Johannes Kepler analyzed Tycho's measurements of the movement of Mars. He discovered that Mars moves in an *ellipse,* a type of squashed circle, with the sun at a key point inside the ellipse. Kepler also found a relationship between how far Mars is from the sun and how rapidly it moves. He concluded that all planets have elliptical orbits and that the relationship between distance from the sun and speed applies to all the planets. These findings, which became known as Kepler's first two laws of planetary motion, were published

in 1609. In 1619, Kepler published his third law, which shows the relation between the sizes of the planets' orbits and the time they take to orbit the sun.

Thus, by the early 1600's, astronomers had used observations made with the unaided eye to determine the movement of the planets. But the Italian astronomer and physicist Galileo had already built and used the first of the great "aids to the eye," the optical telescope, ushering in the era of modern astronomy.

Modern astronomy

Today's astronomers gather information in four major ways: (1) they use telescopes and other instruments to detect visible light and other forms of radiation that are *emitted* (sent out) by celestial objects; (2) they detect particles called neutrinos and cosmic rays from outer space; (3) they study chunks of matter that originated in outer space; and (4) they send spacecraft to land on other objects or to study them close-up.

Using these techniques, modern astronomers have made discoveries beyond the imagination of the ancients. They have discovered three planets outside the orbit of Saturn—Uranus, Neptune, and Pluto. They have found that more than 50,000 smaller bodies called *asteroids* revolve about the sun, most of them between the orbits of Mars and Jupiter. Astronomers have learned that the sun is merely one of hundreds of billions of stars in a vast, disk-shaped galaxy, the Milky Way. They now understand that many of the fuzzy spots visible with telescopes in the night sky are other galaxies.

In addition, astronomers have discovered exotic objects called *pulsars* and *quasars* that emit vast amounts of energy. They have found evidence of *black holes,* objects from which nothing—not even light—can escape.

The stars and constellations of the Northern Hemisphere

This map shows the sky as it appears from the North Pole with Polaris, the North Star, directly overhead. To use the map, face south and turn the map so that the current month appears at the bottom. The stars in about the bottom two-thirds of the map will be visible at some time of the night from most areas of the United States and southern Canada.

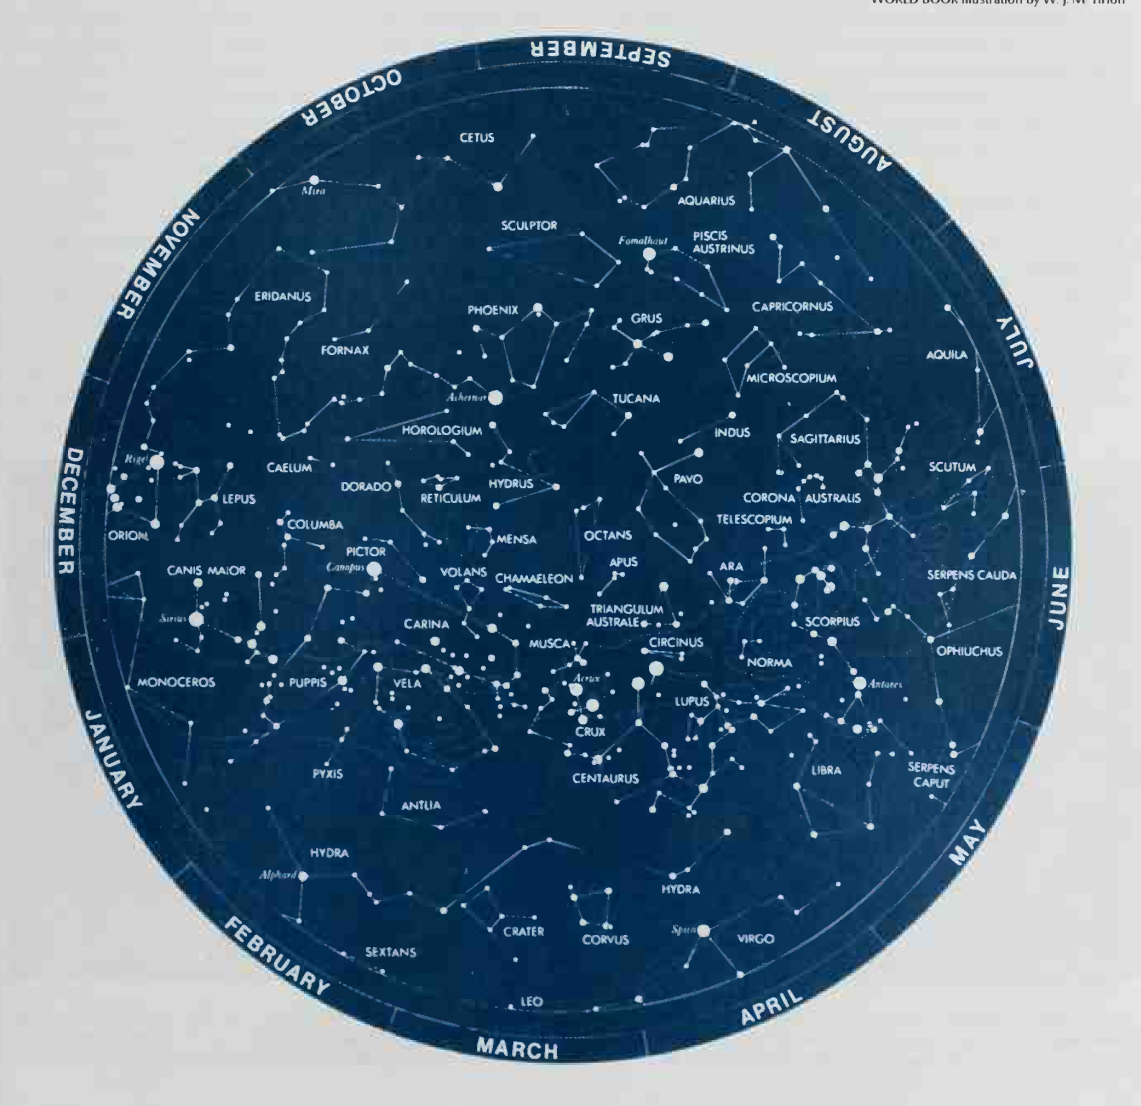
WORLD BOOK illustration by W. J. M. Tirion

They have studied exploding stars called *supernovae.*

Units of distance. Many distances involved in astronomy are so huge that they are measured in special units. One such unit is the *light-year,* the distance that light travels in a vacuum in a year. This distance equals about 5.88 trillion miles (9.46 trillion kilometers). The nearest star, Proxima Centauri, is about 4 light-years from Earth. The Milky Way is about 100,000 light-years across, and the sun is roughly 25,000 light-years from its center. The nearest large galaxy is the Andromeda Galaxy, which is about 2 million light-years away. Some galaxies are more than 10 billion light-years distant.

Astronomers measure distances in the solar system in *astronomical units* (AU). One AU is the average distance from Earth to the sun—about 93,000,000 miles (150,000,000 kilometers). This distance equals about 8 light-minutes. The average distance from the sun to Pluto, the farthest planet, is about 39.5 AU.

In their work with extremely long distances, astronomers use a unit called a *parsec,* rather than the light-year. The parsec is based on *parallax,* an angular measurement. One parsec equals about 3.26 light-years.



Locating objects in space. Astronomers still use two concepts developed by the ancients to specify locations of celestial objects: (1) an imaginary *celestial sphere* and (2) the constellations.

The celestial coordinate system. Astronomers specify locations in terms of the *celestial coordinate system,* a set of imaginary lines drawn on the *celestial sphere.* The celestial sphere is similar to the outermost shell in Aristotle's system—the shell that was thought to carry the stars. The lines are similar to the lines of longitude and latitude used by geographers. The poles of the celestial sphere are the *celestial north pole* and the *celestial*

The stars and constellations of the Southern Hemisphere

This map shows the sky as it appears from the South Pole. There is no "South Star," but the constellation Octans would be almost directly overhead if you were at the South Pole. To use the map, an observer in the Southern Hemisphere would face north and turn the map so that the current month appears at the bottom.

WORLD BOOK illustration by W. J. M. Tirion

south pole, which lie over Earth's north and south geographic poles. The sphere also has a *celestial equator* over the earthly equator.

Longitude in the sky, marked by half-circles going from the north celestial pole to the south celestial pole, is called *right ascension.* Latitude in the sky, marked by circles parallel to the celestial equator, is known as *declination.* Declination north of the celestial equator is positive, while declination south of the equator is negative.

Using the constellations. To locate and assign names to stars, astronomers have divided the sky into 88 parts, each associated with a constellation. Astronomers still use a system developed in the early 1600's to identify the brightest stars in the constellations. The brightest star of all in a constellation is usually designated by alpha, the first letter of the Greek alphabet; the second brightest by beta, the second letter; and so forth. The brightest star in the constellation Orion is thus Alpha Orionis. *Orionis* means *of Orion* in Latin.

Because the Greek alphabet has only 24 letters, this system is limited to 24 stars per constellation. Later astronomers developed naming systems in which numbers are assigned to fainter stars and Roman letters to *variable stars* (stars that vary in brightness).

Electromagnetic radiation is the most plentiful source of information about heavenly bodies. Its name comes from the fact that it consists of waves of electric and magnetic energy. Visible light is electromagnetic radiation, and objects in space also emit many kinds of invisible electromagnetic radiation. Scientists can identify the various forms of this radiation by their wavelength, frequency, or energy.

Wavelength is the distance between successive crests of a wave. From the shortest wavelength to the longest, the forms of electromagnetic radiation are gamma rays, X rays, ultraviolet rays, visible light, infrared rays, and radio waves. Arranged in order of wavelength, the forms make up the *electromagnetic spectrum.*

Frequency. All electromagnetic radiation travels at the same speed. Therefore, a relatively short wave passes a given point more quickly than does a relatively long wave. Thus, more of the shorter waves pass that point each second. Scientists say that a shorter wave has a higher *frequency.* The unit used to measure frequency is the *hertz* (symbol Hz). One hertz represents the passing of one wave past a point in one second.

Energy. According to quantum theory, a cornerstone of modern physics, electromagnetic radiation can also be thought of as particles of energy called *photons.* The amount of energy of a given photon depends on the wavelength—or frequency—of the corresponding wave. Radiation that has a relatively short wavelength and therefore a relatively high frequency also has relatively high energy. Radiation with a relatively long wavelength has a relatively low frequency and relatively low energy.

Optical astronomy is the study of the heavens by de-

Units of astronomical distance

1 astronomical unit	=	150.0 million kilometers	=	93.0 million miles	=	0.0000158 light-years	=	0.00000485 parsecs
1 light-year	=	9.46 trillion kilometers	=	5.88 trillion miles	=	63,200 astronomical units	=	0.307 parsecs
1 parsec	=	30.9 trillion kilometers	=	19.2 trillion miles	=	206,000 astronomical units	=	3.26 light-years

Sizes of astronomical objects

The photographs on this page and the next illustrate the great variation in the size of objects that many astronomers investigate—planets, stars, galaxies, and groups of galaxies. Other astronomers study bits of matter as small as the grains of dust and the molecules of gases between stars, while specialists known as *cosmologists* study the structure of the universe as a whole.

NASA NSSDC

Earth has a diameter of about 7,900 miles (12,700 kilometers). The diameter of Jupiter, the biggest planet in our solar system, is more than 11 times as large as the diameter of Earth.

NASA NSSDC

The sun is a star with a diameter of approximately 864,000 miles (1,390,000 kilometers), about 109 times the diameter of Earth. The largest stars have a diameter about 1,000 times that of the sun.

The electromagnetic spectrum

	Wavelength*	Frequency, hertz†	Sources
Radio waves	1 millimeter and up	Up to 3.00×10^{11}‡	Pulsars; quasars; gas clouds orbiting the center of the Milky Way
Infrared rays	700 nanometers§ to 1 millimeter	3.00×10^{11} to 4.29×10^{14}	Stars in the process of forming; relatively cool stars; planets
Visible light	400 to 700 nanometers	4.29×10^{14} to 7.50×10^{14}	Planets; stars; galaxies; asteroids; comets
Ultraviolet rays	10 to 400 nanometers	7.50×10^{14} to 3.00×10^{16}	Hydrogen gas between the stars; the sun
X rays	0.1 to 10 nanometers	3.00×10^{16} to 3.00×10^{18}	The sun's corona; disks of material around black holes; quasars
Gamma rays	Up to 0.1 nanometer	3.00×10^{18} and up	Collapsed stars; matter-antimatter annihilations

* The ranges indicated are typically used by astronomers to distinguish between forms of electromagnetic radiation. Scientists working in other fields may use slightly different numbers
† One hertz is one cycle of vibration per second.
‡ The small numeral next to the 10 indicates how many places the decimal point is moved to the right when the number is written out. For example, 3.00×10^{11} equals 300,000,000,000.
§ One nanometer is 1 billionth of a meter.

tecting and analyzing visible light. Visible light of different wavelengths has different colors. The wavelengths range from about 400 *nanometers* for deep violet to 700 nanometers for deep red. One nanometer equals a billionth of a meter, or $\frac{1}{25,400,000}$ inch.

Modern observational astronomy began with Galileo's observations of the sky through an optical telescope. Today, astronomers often use observations made with visible light together with observations made in other parts of the electromagnetic spectrum. Astronomers use optical telescopes to observe objects ranging from nearby cool bodies, such as planets, to hotter objects, such as the sun and stars, and to extremely hot objects, such as supernovae.

An optical telescope gathers and focuses light with a lens or mirror. To study the brightest objects, such as the sun, a telescope with a lens or mirror only a few inches or centimeters across may do. For the faintest objects, a much larger light-collecting area is needed. The largest all-purpose telescopes now in general use include the twin Keck Telescopes on Mauna Kea, an extinct volcano on the island of Hawaii. Each telescope has a mirror 33 feet (10 meters) in diameter.

Major optical telescopes are installed on mountains so that starlight does not have to travel far through the atmosphere. These locations minimize blurring due to the atmosphere. The atmosphere bends light due to a phenomenon known as *refraction*, and the atmosphere is constantly moving. As a result, starlight jiggles about and changes in brightness as it passes through the air. Thus, stars appear to twinkle. Twinkling blurs images.

Only a telescope operating in space can avoid blurring entirely. The largest orbiting telescope is the Hubble Space Telescope, which was launched in 1990, repaired in 1993, and upgraded in 1997. This telescope's main mirror measures 94 inches (2.4 meters) across. Because of the size of its mirror and its location above almost all of the atmosphere, the Hubble Space Tele-

Markarian's Chain of galaxies is about 70 million light-years away. At that distance, the width of the space shown in this photo is 2 ½ million light-years—25 times the Milky Way's diameter.

The Very Large Array radio observatory in Socorro, New Mexico, consists of 27 movable dish antennas, each 82 feet (25 meters) across. The arrangement of dishes can extend up to 22 miles (35 kilometers). Computers can combine signals from the antennas to produce images with the detail that would be provided by a single telescope 22 miles across.

National Radio Astronomy Observatory

National Radio Astronomy Observatory

An astronomer studies an image produced by the Very Large Array of radio telescopes. The colors in the "painting" represent different amounts of radio energy sent out by objects in the sky.

scope can produce images that are approximately five times smaller in detail than images made from telescopes on Earth's surface.

Professional astronomers rarely look through telescopes. Instead, they study photographic images. Astronomers began to photograph images through telescopes in the 1850's. The use of long exposure times revealed faint objects that the eye could not see through a telescope. But film has largely been replaced by electronic devices that can detect and record even fainter light. The *charge-coupled device* (CCD), for example, is about 50 times or more sensitive to light than film is.

Optical astronomers have developed three special techniques that have also been used in other kinds of astronomy: (1) *spectroscopy*, (2) *interferometry*, and (3) *adaptive optics*.

Spectroscopy is the breaking down of the incoming radiation into a spectrum of its parts. The spectrum of visible light, for example, is a rainbowlike band of colors. At one end is red, which has the longest wavelength. At the other end is violet, with the shortest wavelength. Spectroscopy is based on a discovery made in 1814 by German optician Joseph von Fraunhofer: The spectrum of the colors of sunlight contains dark lines where specific colors are absent. Later, scientists discovered that light from other stars also has such dark lines. When the object emitting the light is a hot gas, the spectrum has bright lines. Other kinds of electromagnetic radiation from celestial objects also have spectral lines.

Studies of spectral lines reveal the temperature, density, and chemical composition of the object emitting the radiation. The spectral lines arise in energy processes in atoms. An electron orbiting an atomic nucleus can have only certain definite levels of energy. These levels can be thought of as stairsteps. When light energy passes through a group of atoms, the electrons can absorb just the right amount of energy to jump from a lower step to a higher one. Because the energy is removed from the passing light, a kind of spectral line called an *absorption line* appears in the spectrum. The dark lines discovered by Fraunhofer were absorption lines. Each kind of atom has its own pattern of absorption lines for a given range of temperature.

Bright spectral lines called *emission lines* occur when electrons in atoms of hot objects "jump down the stairs" by emitting energy. In the early 1940's, an analysis of emission lines confirmed an earlier discovery that the sun's *corona*, the outer edge of its atmosphere, has a temperature of millions of degrees.

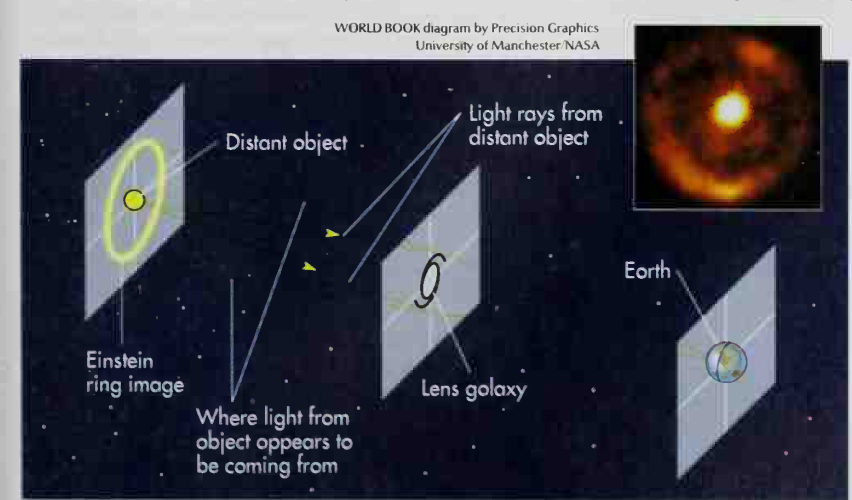
The entire band of radiation emitted by the surface of a star also contains information about the star's temperature. Relatively cool stars are red-hot and can appear slightly reddish to the eye. Hotter stars can become blue-white.

Spectroscopy can even reveal the distance to a star or galaxy. In the spectrum of any moving object, the spectral lines are shifted from where they would appear in the spectrum of a stationary object. Such shifts are interpreted in terms of the *Doppler effect*. One familiar example of this effect is a change in the pitch of sound waves emitted by a vehicle. For example, when a car approaches you, the pitch of the sound made by the engine is higher than it is when the car is going away. The shift of

A combined optical and radio image shows radiation produced by what is probably a huge black hole in the center of a galaxy. Objects fall into the black hole, generating energy. The galaxy sends out the energy as visible light, shown in blue, and as radio waves, artificially colored red. The total distance from left to right is about 2 million light-years.

National Radio Astronomy Observatory

spectral lines also depends on whether the object is approaching or receding. If the lines shift toward the blue (shorter-wavelength) end of the spectrum, the object is approaching. If they shift toward the red (longer-wavelength) end, the object is moving away.

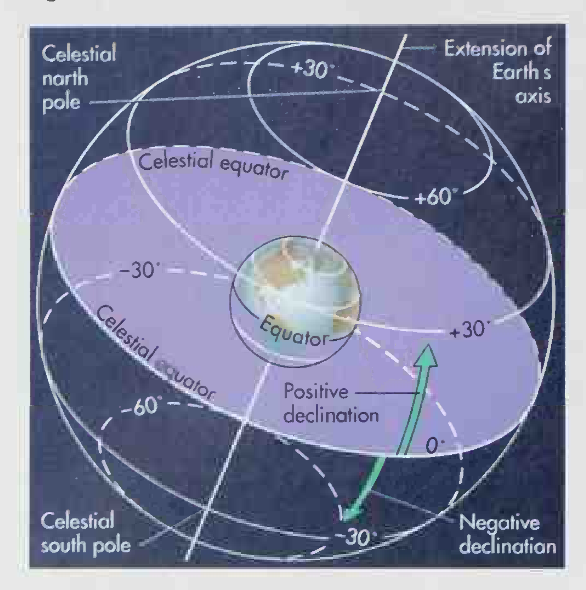


In 1929, the American astronomer Edwin Hubble discovered that the farther away a galaxy is, the faster it is retreating, and thus the greater is its redshift. Thus, astronomers can determine the distance of a remote galaxy by measuring its redshift.

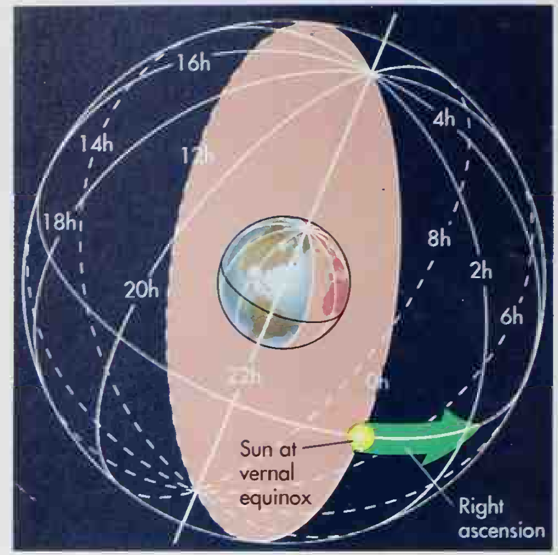
Interferometry uses a phenomenon called *interference* in which rays of light combine to form a pattern. Astronomers use such patterns, often with the aid of computers, to produce extremely detailed images. In the simplest example in optical astronomy, a ray of light emitted by a star strikes the mirror of a telescope, and another ray emitted by the same star strikes the mirror of a nearby telescope. Optical and mechanical devices combine the rays so that a series of bright and dark bands of light called an *interference pattern* appears. For an explanation of why this pattern appears, see the article **Interference**. The pattern reveals any difference in the routes taken by the rays as they travel from the star to the telescopes. For example, if the rays were emitted at opposite edges of the star, the pattern could reveal the diameter of the star. A computer helps astronomers analyze the interference pattern and use the results to produce an image.

Adaptive optics can make up for atmospheric blurring in ground-based telescopes. In this technique, light reflects from a telescope's main mirror to a special deformable mirror, then to a CCD. Pistons mounted on the underside of the deformable mirror can change its shape several hundred times a second to make up for atmospheric blurring. A special control system senses the amount of blurring and operates the pistons.

In one arrangement, the deformable mirror is in the main telescope and the control signals come from a smaller auxiliary telescope. A laser beam emitted by the auxiliary telescope reflects off atoms in the atmosphere and returns to the auxiliary telescope. As the beam travels, the atmosphere distorts it slightly. A computer analyzes the reflected beam, then operates the pistons in a way that would remove the distortion from the image of the beam. This operation removes much of the distortion in the image viewed by the main telescope.

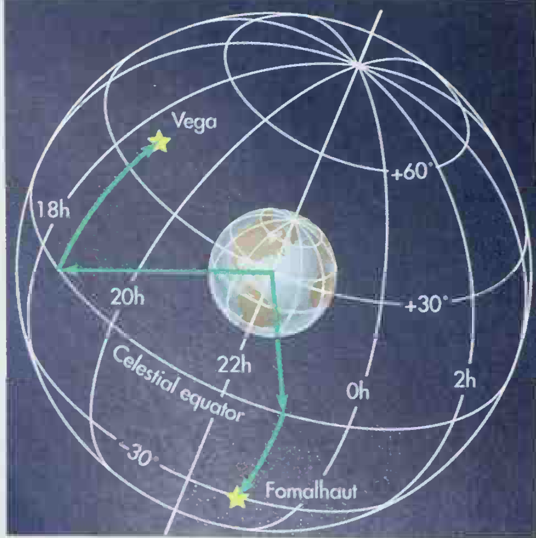


WORLD BOOK diagram by Precision Graphics
University of Manchester/NASA



Gravitational lensing occurs when the gravitational force of a massive galaxy apparently acts as a lens, bending light rays sent out by an object on the other side of the galaxy. The light from the distant object appears to come from an arc or, as shown in the inset photo, a ring. Such rings are called Einstein rings—named after physicist Albert Einstein, who described how gravitation seems to bend light.

Locating a star by declination and right ascension



Astronomers locate objects in the sky by means of a *celestial coordinate system.* All the objects are considered to lie on an imaginary sphere surrounding Earth. Astronomers specify a location in terms of an angle measured from a horizontal circle and an angle measured from a vertical circle.

Vertical angles are measured northward and southward from the *celestial equator,* which lies above Earth's equator. A vertical angle is known as a *declination* and can be positive or negative.

Horizontal angles are measured eastward from the *vernal equinox,* where the sun crosses the celestial equator. An angle, or *right ascension,* is given in hours, minutes, and seconds.

WORLD BOOK diagrams by Precision Graphics

Celestial coordinates locate the star Vega at right ascension (RA) 18 hours 36 minutes 56.3 seconds and at declination (Dec) +38 degrees 47 minutes 1 second. Astronomers give the coordinates of the star Fomalhaut as RA 22h57m39.1s, Dec −29°37′20″.

Infrared astronomy deals with invisible electromagnetic waves whose wavelengths are longer than those of visible light. Objects that are bright in infrared wavelengths include relatively cool stars and stars in the process of forming. Planets and other objects that glow by reflecting sunlight or starlight are also best studied in the infrared spectrum.

The infrared spectrum covers a range from about 700 nanometers to 1 millimeter. Infrared astronomers commonly express wavelengths in *micrometers* (thousandths of a millimeter), specifying the overall range as about 0.7 to 1,000 micrometers.

A photon of infrared radiation has less energy than a photon of visible light. Most infrared photons do not have enough energy to cause the chemical reaction that produces images on film. Infrared astronomy therefore did not develop fully until about the 1960's, when electronic sensors that could produce infrared images were introduced.

One problem with infrared astronomy is that Earth's atmosphere absorbs rays of most wavelengths in the infrared spectrum. However, some of the shorter waves can be detected at mountaintop observatories. Notable infrared telescopes include the Infrared Telescope Facility of the National Aeronautics and Space Administration (NASA) of the United States and the United Kingdom Infrared Telescope. Both are on Mauna Kea. The telescopes are above most of the water vapor in Earth's atmosphere, one of the main absorbers of infrared rays.

In 1997, an infrared astronomy project called the Two Micron All Sky Survey (2MASS) began under the direction of the University of Massachusetts. Telescopes at Mount Hopkins, which is near Tucson, Arizona, and at Cerro Tololo, a mountain in Chile, are mapping the sky at a wavelength of 2 micrometers.

For 10 months in 1983, a multinational orbiting telescope called the Infrared Astronomical Satellite (IRAS) mapped infrared radiation across the entire sky. In 1995, the Infrared Space Observatory, a European spacecraft,

took up where IRAS had left off, surviving until 1998.

An orbiting infrared telescope has a limited useful life because it must be cooled artificially. Its lifetime is limited by the amount of coolant it carries. Cooling is necessary to prevent the telescope's own infrared radiation from overwhelming the faint rays coming from outer space. The telescope must be cooled to the temperature of liquid helium—about 4 Celsius degrees above *absolute zero* (−459.67 °F or −273.15 °C). Absolute zero is the theoretical temperature at which atoms and molecules would have the least possible energy.

In 1989 and 1990, a satellite called the Cosmic Background Explorer (COBE) mapped the sky at the longest infrared wavelengths. In 1997, astronauts installed a device called the Near Infrared Camera/Multi-Object Spectrometer on the Hubble Space Telescope.

Radio astronomy. Astronomers use radio waves emitted by celestial objects to produce images of the objects and to study the objects spectroscopically. These are the same kinds of waves that radio and television broadcasters create to transmit programs—astronomers just use them differently.

The radio spectrum includes all electromagnetic waves longer than about 1 millimeter. Waves longer than about 1 millimeter and shorter than about 10 meters pass readily through Earth's atmosphere. Astronomers receive radio signals from a wide variety of objects, including particles swirling in the magnetic field of Jupiter, gas clouds orbiting the center of the Milky Way, *pulsars* (rapidly spinning collapsed stars from which regular bursts of radiation are received), distant galaxies, and *quasars*. A quasar is a distant object that produces an enormous amount of radiation. Almost all astronomers believe that a quasar is powered by an enormous black hole at the center of a galaxy.

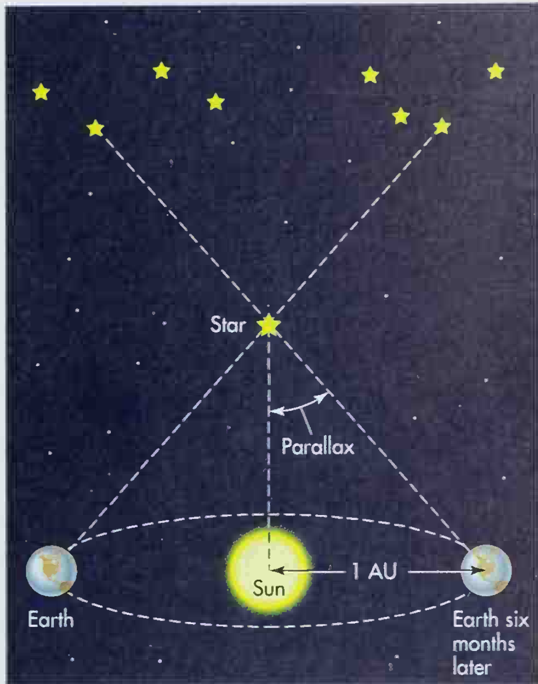
Karl G. Jansky, an American engineer, discovered radio waves from outer space in 1931. The science of radio astronomy was not established until after World War II (1939-1945), however.

A radio telescope is essentially a large dish antenna. Unlike the reflecting surfaces of other kinds of telescopes, the dish surface does not have to be extremely smooth. The smoothness required of a reflecting surface depends on the length of the waves to be reflected. The shorter the wavelength is, the smoother the surface must be. Because radio waves are long, some dish surfaces are even made of metal mesh.

The largest radio telescopes that can be steered to point anywhere in the sky are 328 feet (100 meters) in diameter. One is in Effelsberg, Germany, near Bonn. The other is in Green Bank, West Virginia. The largest radio telescope of all is a nonsteerable telescope near Arecibo, Puerto Rico. Its reflecting mesh covers a natural bowl in the ground 1,000 feet (305 meters) in diameter.

Radio astronomy is the field in which interferometry is most useful. To use separate telescopes as an interferometer, the distance between them must be controlled to a fraction of the wavelength of the radiation to be detected. This requirement severely limits the use of interferometry in the other branches of observational astronomy, where wavelengths are shorter. Because radio waves are so long, however, the dishes of radio interferometers can be ten, hundreds, or even thousands of miles or kilometers apart.

NASA JPL



The Mars Odyssey probe, launched in 2001, found evidence of water ice beneath the surface of Mars in 2002. The probe also analyzed the chemical composition of the Martian surface.

The Very Large Array (VLA) in Socorro, New Mexico, links 27 movable dishes, each 82 feet (25 meters) in diameter. The telescopes move along railroad tracks built in the shape of a Y. Individual dishes can be up to 22 miles (35 kilometers) apart. The Very Long Baseline Array (VLBA) consists of 10 telescopes, each 82 feet across, spread across one side of Earth. Their locations range from the Virgin Islands north to New Hampshire and west to Hawaii. As an interferometer, the VLBA is equivalent to a single telescope with a diameter roughly equal to the diameter of Earth.

Astronomers have learned much by studying redshifts and blueshifts in spectral lines. Because the radio spectrum is not visible, astronomers see these "lines" as low and high points in a graph of wavelength. The low points represent wavelengths of radiation absorbed by celestial objects. The high points represent wavelengths of radiation emitted by strong radio sources.

Redshift and blueshift work with radio waves exactly as they work with waves of visible light: If the lines in the spectrum of radiation emitted by an object shift toward the shorter-wavelength end, the object is approaching. The object is said to be blueshifted. If the lines shift toward the longer-wavelength end, the object is moving away and is said to be redshifted.

Astronomers have analyzed redshifts and blueshifts in radio radiation emitted by gas clouds in the Milky Way Galaxy. Their analysis showed how rapidly the galaxy is rotating and how the speed of the revolution of its stars changes with the stars' distance from the galactic center. The astronomers then applied a formula relating the

WORLD BOOK diagram by Precision Graphics

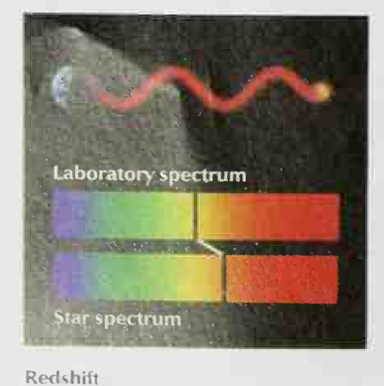
Parallax is the angle by which a star's location relative to background stars differs when measured from two points 1 astronomical unit (AU) apart and on a line perpendicular to the line from the star. One AU is the distance from Earth to the sun—about 93 million miles (150 million kilometers). Parallax is thus half the difference seen from opposite sides of Earth's orbit.

speed of the stars' revolution to the stars' masses. They discovered that the amount of mass in the galaxy is about 1 trillion times the mass of the sun.

Both radio astronomers and optical astronomers have studied a phenomenon known as *gravitational lensing.* This phenomenon occurs, for example, where radiation emitted by a small, distant galaxy passes near a massive galaxy that is between the object and Earth. The gravitational force of the galaxy apparently bends the radiation much as an ordinary optical lens bends light rays that pass through it. Gravitational lensing can produce an image of the small galaxy in the shape of an arc or even a ring. Astronomers can study the radiation in the arc or ring to learn about the small galaxy.

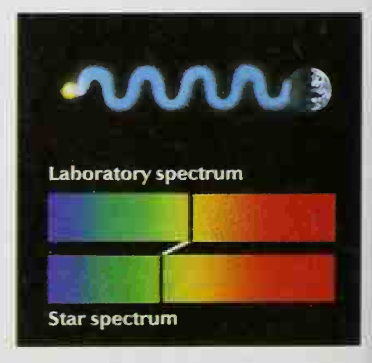
Ultraviolet astronomy. The ultraviolet part of the electromagnetic spectrum has wavelengths shorter than those of visible light. Wavelengths of ultraviolet light range from near the limit of the shortest waves that the eye can see, about 400 nanometers, down to about 10 nanometers. Radiation from 400 to 300 nanometers (near ultraviolet) passes through Earth's atmosphere and therefore can be detected on the ground. But ultraviolet astronomers get much of their information from shorter wavelengths—in the *far ultraviolet,* from 300 to about 100 nanometers; and in the part of the *extreme ultraviolet* from 100 to 10 nanometers.

Studies in the far and extreme ranges must be carried out by satellites. From 1978 to 1997, the International Ultraviolet Explorer studied wavelengths from 320 down to 115 nanometers. NASA sent the Extreme Ultraviolet Explorer aloft in 1992 to study wavelengths of 7 to 76 nanometers. In 1999, NASA launched the Far Ultraviolet Spectroscopic Explorer to observe wavelengths of about 90 to 120 nanometers.



The largest and most sensitive ultraviolet telescope in orbit is the Hubble Space Telescope. Astronomers have used this telescope to study hydrogen gas, whose strongest spectral lines are in the ultraviolet spectrum. The researchers have studied both normal hydrogen and a heavy form known as *deuterium* in the space between the sun and nearby stars. All this deuterium formed in the first 1,000 seconds after the *big bang,* the explosion that began the universe. Astronomers understand how the amount of deuterium that formed is related to present amounts of other kinds of matter. Knowing the amount of deuterium in space therefore can help them determine the density of the universe.

Another space telescope is the Solar and Heliospheric Observatory (SOHO), which orbits between Earth and the sun. The European Space Agency launched SOHO in 1995 to monitor the sun with visible-light and ultraviolet cameras and spectrographs. NASA provided some of this equipment. Highly detailed images from SOHO show the sun in, for example, the ultraviolet light of helium gas at 60,000 °C or iron gas at 1,500,000 °C. NASA's Transition Region and Coronal Explorer (TRACE) is sending images that are even more detailed.



X-ray astronomy. X rays have wavelengths from about 10 nanometers down to about 0.1 nanometer. The

Detecting redshift and blueshift

Astronomers can learn about a star's motion by comparing the spectral lines in its visible light with those in a spectrum produced in a laboratory. If the star's spectral lines are shifted toward the red end of the rainbowlike spectrum of colors, the star is moving away from Earth. If the lines are shifted toward the blue end, the star is approaching. Astronomers use a similar technique to analyze shifts in the spectral "lines" of invisible forms of radiation, such as infrared and ultraviolet rays.

Redshift

Blueshift

WORLD BOOK illustrations by Ernest Norcia

hottest regions in space produce X rays. These regions include the sun's corona and disks of material around black holes. The material in these disks heats up due to friction as it spirals into the black holes. As the material heats up, it emits X rays. The hot gas at the center of clusters of galaxies also emits X rays. Quasars are another source of X rays.

Celestial X rays do not penetrate Earth's atmosphere and therefore can be studied only from spacecraft. X rays would pass through ordinary telescope mirrors and lenses, so one kind of X-ray telescope has specially designed mirrors. X rays strike these mirrors at low angles, then skip away like stones skipping off water. Rays from all the mirrors meet at a single focal point.

Other X-ray telescopes do not have mirrors. The rays enter the telescope through openings between lead or iron slats, then strike special detectors.

In the 1970's and 1980's, a series of High-Energy Astronomy Observatories mapped the sky in X rays and studied certain objects in detail. From 1990 to 1998, a German-U.S.-British spacecraft named Rosat surveyed the sky. In 1995, NASA launched the Rossi X-ray Timing Explorer. A Japanese satellite, Yohkoh, sends back X-ray images of the sun that show the corona and solar flares, explosive events that reach millions of degrees.

In July 1999, NASA launched the Chandra X-ray Observatory from the space shuttle Columbia. Chandra can produce much more detailed images than any other X-ray telescope. In December 1999, The European Space Agency used an Ariane 5 rocket to launch an X-ray observatory known as XMM-Newton. This satellite's telescopes can detect much fainter X-rays than Chandra can, though with lower resolution.

Gamma-ray astronomy. Electromagnetic waves that have the shortest wavelengths—about 0.1 nanometer and shorter—are known as gamma rays. Gamma-ray photons have the highest energy in the electromagnetic spectrum. Thus, they form in the regions of the highest energy in the universe.

Gamma-ray sources include places where matter and *antimatter* are annihilating each other. For every type of ordinary subatomic particle, there also exists an antiparticle. An antiparticle has the same amount of *mass* (total matter) as its corresponding particle, but it carries an opposite electric charge. For example, the antiparticle of an electron is a *positron*. An electron carries a negative charge, while a positron carries a positive charge. If a particle and its antiparticle collide, they annihilate each other, releasing gamma rays and other energy.

Astronomers have observed that matter-antimatter annihilation occasionally occurs near the center of the Milky Way. Other gamma-ray sources include the Crab Nebula, in the constellation Taurus, and a nearby collapsed star known as Geminga. The Crab Nebula consists of matter that was thrown out into space during a supernova observed in A.D. 1054.

The Compton Gamma Ray Observatory, which was in orbit from 1991 to 2000, had several gamma-ray instruments. One detector followed up on an earlier discovery of gamma-ray bursts that apparently come at random intervals from random places in the sky. The instrument detected one gamma-ray burst approximately every day.

In October 2000, an international team of research centers launched the High Energy Transient Explorer-2 (HETE-2) satellite to detect and locate gamma-ray bursts. HETE-2 carries a gamma-ray detector and two X-ray detectors. When the satellite detects a gamma-ray burst, it computes the location of the source and sends this information to ground stations around the equator. The stations forward the data to a control center at Massachusetts Institute of Technology. Within seconds, the center sends the data to ground-based observers so that they can study the source with optical telescopes.

Neutrino astronomy. Another type of particle that arrives from outer space is the neutrino. Neutrinos rarely interact with particles on Earth. Neutrino detectors therefore use large amounts of matter as targets for the neutrinos. One detector, called Super-Kamiokande, is deep underground in a mine in Japan. Its main part is a cylindrical tank of water that measures 131 feet (40 meters) deep and 131 feet in diameter. Electronic devices in the detector can sense flashes of light produced when a neutrino collides with an atomic nucleus or an electron in the water. This detector began operating in 1996.

The most sensitive neutrino detector is the Sudbury Neutrino Observatory (SNO), in a mine near Sudbury, Ontario. The facility uses 1,000 tons of *heavy water*. In heavy water, the nucleus of each hydrogen atom consists of a proton and a neutron, instead of only a proton. SNO began taking measurements in 1999.

Beginning in the 1960's, scientists working with an older kind of detector found that certain neutrinos were "missing." These neutrinos were *electron-neutrinos* created by nuclear reactions in the sun. Electron-neutrinos are one of three kinds of neutrinos known to exist. The others are *muon-neutrinos* and *tau-neutrinos*. The scientists measured only about one-half to one-third of the expected number of electron-neutrinos from the sun.

Physicists suspected that the missing electron-neutrinos change into muon-neutrinos and tau-neutrinos on their way to Earth. In 2001, scientists at Sudbury claimed that a comparison of measurements made there and at Super-Kamiokande shows that the change does occur.

Cosmic-ray astronomy. Cosmic rays are electrically charged, high-energy particles. There are two kinds of cosmic rays: (1) *primary cosmic rays,* often called *primaries,* which originate in outer space; and (2) *secondary cosmic rays,* or *secondaries,* which form in Earth's atmosphere. Secondaries originate when primaries collide with atoms at the top of the atmosphere.

Most primaries are protons or other nuclei of atoms. They do not usually penetrate the atmosphere. Astronomers therefore use instruments aboard high-flying airplanes or satellites to detect them. Secondaries can reach low altitudes. A small fraction of them even strike Earth's surface, where special sensors can detect them.

Some primary cosmic rays come from the sun, but most of them are *galactic cosmic rays,* which originate outside the solar system. Many galactic cosmic rays have tremendous energy. This energy may come from supernova explosions.

Gravitational-wave astronomy. Astronomers are building equipment to detect another type of radiation: gravitational waves. These waves are predicted by the general theory of relativity announced in 1915 by German-born physicist Albert Einstein. No gravitational waves have ever been directly detected. Researchers have found indirect evidence for them, however—cer-

tain variations in the orbits of two dense stars that revolve about each other.

Direct sampling is the examination of pieces of material from celestial objects. In their examinations, scientists often use techniques of geology, including chemical analysis. The most common samples are *meteorites,* rocks that fell through the atmosphere from farther out in our solar system. Thousands of meteorites have been found. Most come from asteroids, and only a handful are known to have come from the moon or Mars. The best place to find meteorites is Antarctica. They can be seen on the polar ice much more easily than they can be detected among ordinary rocks at other locations.

Scientists have also studied hundreds of kilograms of moon rocks brought to Earth by astronauts from 1969 to 1972. In 1970, the Soviet Union's Luna 16 spacecraft, a remotely controlled vehicle, returned small samples of soil from the moon. In addition, researchers have analyzed bits of space dust collected by devices on high-altitude aircraft. They have determined that some of the dust came from beyond our solar system.

Computer modeling

Astronomers use computers to build *scientific models* (sets of mathematical equations) that represent certain processes, such as the formation of a star. After entering the equations into a computer, an astronomer inserts numbers into the equations, and the computer then *simulates* (represents) how the process would develop. In some cases, the computer produces a moving picture on a computer screen. The picture can run much faster than the actual process. This kind of model can help astronomers because many important processes occur much too slowly for astronomers to observe. Other important processes that can be simulated occur in inaccessible places, such as the interiors of stars.

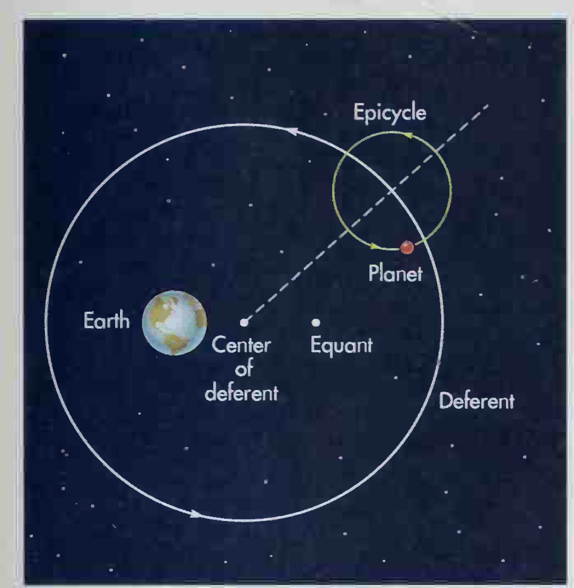
Learning about astronomy

It is easy for students and the general public to take part in astronomy. Amateur astronomers range from individuals who make casual nighttime or solar observations to people for whom astronomy is a serious pursuit. Amateur astronomers have their own associations and local and regional clubs. Some of the larger clubs hold star parties at which members set up their own telescopes and observe the skies.

Amateur astronomers make major contributions to various branches of astronomy. For example, the American Association of Variable Star Observers, whose headquarters are in Cambridge, Massachusetts, collects observations from amateurs throughout the world and puts them together. The association shares the data with professional observers, including astronomers who want to know what certain stars are doing before they conduct observations. Other amateur astronomers search for new comets or supernovae.

Much technical information is available to amateur astronomers. Books on observing the heavens contain tables that indicate where stars and planets can be found each month. Many cities have planetariums, which can present shows demonstrating the movements of celestial objects. Some planetariums sponsor lectures by professional astronomers. Computer programs available on CD-ROM simulate sky conditions for any location and any date and time. Many of the programs contain photographs and motion pictures of astronomical objects. Such images are also available on the Internet.

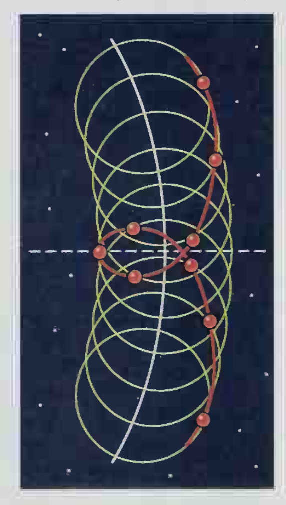
In addition, certain computer programs enable users to combine or enhance existing astronomy photographs. For example, individual images taken at total eclipses can be combined to show the structure of the solar corona in more detail.

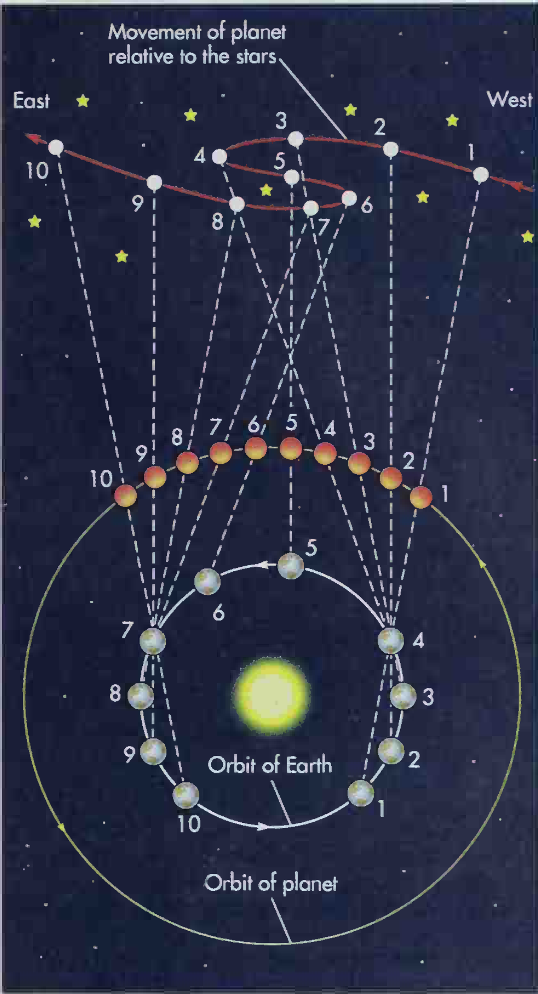


History

The roots of astronomy extend back to the dawn of civilization. More than 4,000 years ago, in what is now England, several generations of people built Stonehenge, an "observatory" consisting of huge, cut stones arranged in circles. Certain stones and alignments of stones appear to mark locations of astronomical importance, such as the point at which the sun rose on the longest day of the year. Stonehenge was apparently also a place of worship.

Some of today's constellations have their roots in pat-





At a star party, amateur astronomers set up their telescopes, chat with friends, and wait for sunset and a night of viewing the heavens. Astronomy clubs throughout the world sponsor star parties.

WORLD BOOK diagram by Precision Graphics

The old theory of Ptolemy put Earth at the center of the universe. Each of the other planets revolved in a circle called an *epicycle*, which revolved along a *deferent*. The epicycle's center moved at a constant speed about a point called an *equant*. This complex movement, *right*, explained why the planets sometimes appear to change direction relative to the stars.

WORLD BOOK diagram by Precision Graphics

The modern explanation is that the planets appear to change direction because of differences in orbital speed as one planet passes another. A planet close to the sun orbits the sun more rapidly than does a more distant planet. In this diagram, each set of three numbers—for example, the three 5's—represents the same moment of time.

terns in the sky noted by the Sumerians in perhaps 2000 B.C. Chinese constellation patterns, which are largely different from those used in Europe, may also date from that time. Babylonian tablets show that astronomers there were noting the positions of the moon and planets by 700 B.C. The Babylonians also noted eclipses.

The ancient Greeks carried forward ideas from the Babylonians and invented some of their own. Aristotle's system of physics and astronomy, developed in the 300's B.C., survived for almost 2,000 years. In Aristotle's system of astronomy, Earth was the center of the universe. During the A.D. 100's, Ptolemy modified Aristotle's system to account for the retrograde motion of the planets. Ptolemy also maintained that Earth was the center of the universe, however.

Developing the modern view. By the early 1500's, Nicolaus Copernicus had developed a theory in which Earth and the other planets revolved about the sun. In the early 1600's, Johannes Kepler analyzed precise measurements of planetary positions that had been made by Tycho Brahe. Kepler then developed three laws that correctly describe the shapes of the orbits of planets, indicate how rapidly a planet moves at various times of its year, and account for the length of the planet's year.

While Kepler based his laws of planetary motion on observations, the English astronomer and mathematician Isaac Newton proved them mathematically. In 1687, Newton completed a book usually called *Principia Mathematica* setting forth not only laws of motion but also the law of gravity that is still in general use.

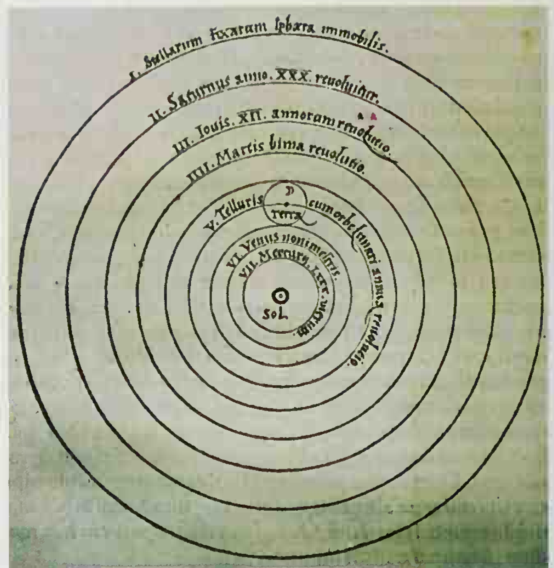
By Newton's time, the field of optical astronomy had already begun. In 1609, Galileo heard that an optical device had been built that made distant objects appear closer. He soon built his own telescope. The discoveries Galileo made with this instrument backed the Copernican theory over the theories of Aristotle and Ptolemy. In 1616, however, the Roman Catholic Church warned

Galileo not to teach that Earth revolves about the sun. A book of Galileo's published in 1632 was interpreted as a violation of the ban, and Galileo was put under house arrest. Only in 1992 did the Catholic Church confirm that Galileo should not have been tried or convicted.

Finding new planets. The British astronomer William Herschel discovered a new object in the sky in 1781. At first, he thought the object was a comet. It turned out to be a planet—later named Uranus. This was the first planet discovered since ancient times.

In 1845, astronomers John C. Adams of Britain and Urbain Leverrier of France declared that another planet must lie a certain distance beyond Uranus. They based their statement on their calculations of differences between the observed orbit of Uranus and the orbit predicted by one of Kepler's laws. They said that this difference was due to the gravitational attraction of the then-unknown planet. Using one of their predictions the next year, the German astronomer Johann G. Galle found the planet, Neptune.

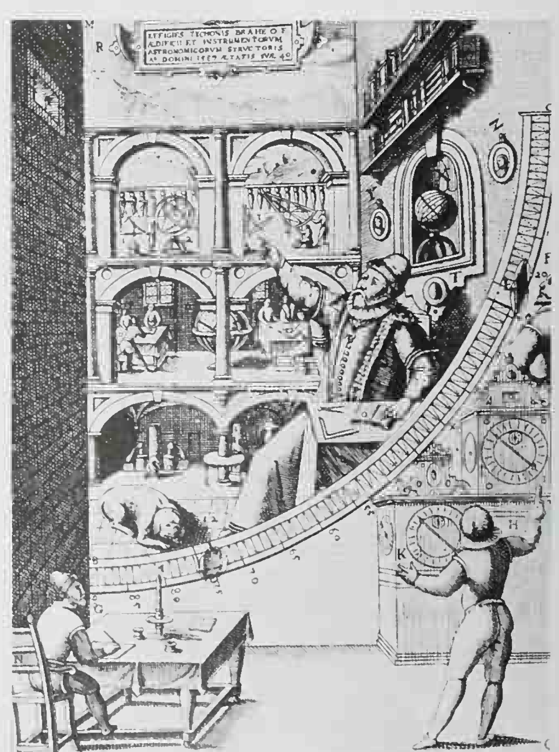
The American astronomer Clyde W. Tombaugh found the last of the known planets in the solar system in 1930. He discovered Pluto on photos he had taken for the purpose. He used a wide-angle telescope at Lowell Observatory in Flagstaff, Arizona.



Discovering other galaxies. In the early days of optical astronomy, the fuzzy regions of the sky became known as *nebulae*—Latin for *clouds*. When viewed through the telescopes then available, the nebulae resembled comets. Someone who was trying to discover comets could easily mistake a nebula for a comet. To prevent such errors, the French astronomer Charles Messier made a list from the 1750's to 1784 of the most prominent nebulae. This *Messier Catalog* now contains 110 objects, known by their *Messier numbers*.

In Messier's time, no one knew what the nebulae were. But in the mid-1800's, Lord Rosse of Ireland built a telescope whose superior light-gathering power enabled him to discover that many nebulae have spiral shapes. The telescope's mirror measured about 6 feet (1.8 meters) across—gigantic for that time.

It took decades to discover what the spiral nebulae were. The answer came only in 1924 with the discovery by Edwin Hubble that the spiral nebulae are so far away that they must be beyond the Milky Way. Astronomers concluded that they are independent galaxies. The "nebula" with Messier number M31, for example, is actually the Andromeda Galaxy. Astronomers now use *nebula* to mean a cloud of dust and gas. The remaining objects in the Messier catalog are *star clusters,* groups of closely placed stars.



Advances in astrophysics. By the end of the 1930's, the German-born physicist Hans Bethe had suggested how nuclear fusion powers the stars. For example, a process known as the *proton-proton chain* powers the sun. In this process, six protons come together in several steps to produce a helium nucleus and two protons. The final products contain slightly less mass than the original ingredients. The missing matter is converted to energy according to Einstein's formula $E = mc^2$, where E is energy, m is the missing mass, and c^2 is the speed of light multiplied by itself.

British astronomers Geoffrey Burbidge, Margaret Burbidge, and Fred Hoyle and American physicist William

The sun-centered theory proposed by Nicolaus Copernicus of Poland in 1543 revolutionized astronomy. This diagram is from his *Concerning the Revolutions of the Celestial Spheres.*

Ann Ronan Picture Library

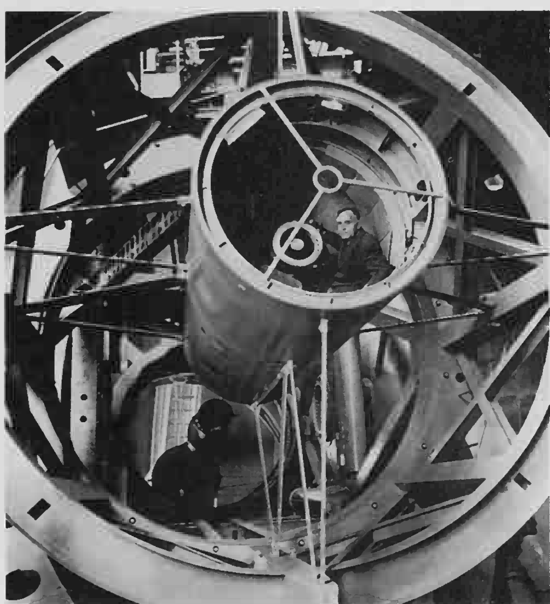
Tycho Brahe's observatory is pictured in this drawing, which dates from 1598. Brahe, a Dane, is shown seated behind his giant *quadrant,* an instrument used to measure the altitude of stars and planets. Brahe's observations of the planets were far more accurate than any previous ones.

A. Fowler showed in the 1950's how nuclear reactions could have built up all but the lightest chemical elements. Astronomers now know that the lighter elements formed minutes after the big bang. Moderately heavy elements formed inside stars; the heaviest elements, in supernova explosions.

In 1965, American physicists Arno Penzias and Robert Wilson discovered faint radio radiation coming equally from all directions in space. Scientists showed that the radiation was emitted about 300,000 years after the big bang and has been cooling ever since. Its temperature is now about 3 Celsius degrees above absolute zero.

For four years starting in 1989, instruments aboard the Cosmic Background Explorer satellite measured more precisely the temperature of the radiation detected by Penzias and Wilson. Another instrument aboard the satellite found small variations in the temperature from one location in the sky to another. These so-called ripples in space may be the "seeds" from which the galaxies and clusters of galaxies grew long ago.

Finding quasars and pulsars. In 1963, the Dutch-born astronomer Maarten Schmidt identified the star-like objects now known as quasars. Schmidt showed that the spectra of quasars have huge red shifts, indicating that the spectra are produced by powerful sources of energy in distant galaxies. Most of them are billions of light-years away.



In 1967, the British astronomer Jocelyn Bell Burnell identified a new type of object in radio observations she was making as part of her Ph.D. thesis. These objects emit radio waves that arrive at Earth in regular pulses about 1 second apart. The objects came to be known as pulsars. Later work showed that pulsars are rapidly spinning *neutron stars* (stars made mostly of neutrons). With every spin, a narrow beam of radio waves sweeps over Earth, producing a pulse. Astronomers have found pulsars that pulse as often as 600 times per second.

Space probes. The United States began to send space probes to other planets and to the moon in the late 1900's. From 1979 to 1981, Voyager 1 and Voyager 2 flew near Jupiter and Saturn. Voyager 2 flew past Uranus in 1986 and Neptune in 1989. Both craft sent back data and photographs that greatly enriched scientists' knowledge of those planets.

The United States has put a number of scientific satellites into orbit around celestial objects. From 1990 to 1994, the orbiter Magellan mapped the surface of Venus with radar. The Galileo spacecraft entered an orbit around Jupiter in 1995 on a mission to explore that planet and several of its satellites. In 1997, the Mars Global Surveyor went into orbit to study Mars's magnetic fields, monitor its weather, and measure visible light and other radiation emitted by the planet. Also in 1997, the United States launched the Cassini mission to study Saturn, its rings, and its satellites. The Cassini craft is due to reach Saturn in 2004. It will drop a probe into the atmosphere of Saturn's moon Titan. Lunar Prospector entered an orbit over the moon's poles in 1998. The spacecraft's mission was to map the mineral composition of the moon.

Careers

What astronomers do. Most professional astronomers work at observatories or research institutes or teach and conduct research at colleges and universities. Planetariums employ astronomers to lecture and conduct classes for the public. A few astronomers work for companies that build equipment for scientific satellites and space probes. Others work for firms that do such work as monitoring the environment from space.

Edwin Hubble, an American astronomer, demonstrated that the universe is expanding. He is shown in the observer's cage of the Hale telescope at the Palomar Observatory near San Diego.

Becoming an astronomer. The most important characteristic for a person who wishes to become an astronomer is a powerful spirit of inquiry. The person should also have a strong ability to learn mathematics.

High-school students who are interested in becoming astronomers should take as many math courses as they can to prepare for college mathematics and physics. A high-school physics course is also useful. Some branches of astronomy deal more with chemistry or geology than physics, so courses in those subjects can also help. Visits to planetariums and science museums as well as participation in an amateur astronomy club can help prepare a student for a career in astronomy. Other useful skills include keyboarding and an ability to work with basic scientific and mathematical software.

To conduct research and teach astronomy at the college level requires a Ph.D. degree. Students usually take about six years to obtain this degree after receiving their bachelor's degree. During most of this time, Ph.D. students perform research, and they are almost always supported through research grants or teaching salaries. After obtaining their degree, most astronomers take postdoctoral positions for two or more years before searching for permanent jobs.

Astronomy associations. Astronomers from throughout the world gather every three years at the General Assembly of the International Astronomical Union. Professionals in the United States and Canada belong to the American Astronomical Society. Both professional and amateur astronomers may join the Astronomical Society of the Pacific. Many countries also have

organizations devoted to astronomy, such as the Astronomical Society of India, the Royal Astronomical Society of Canada, and the United Kingdom's Royal Astronomical Society. Jay M. Pasachoff

Astrophysics is a science that applies principles of physics to many fields of astronomy. Astrophysicists try to determine the physical nature, origin, and development of the solar system, galaxies, and the universe. Almost all astronomers are also astrophysicists.

Astrophysicists use optical telescopes to view celestial objects that give off electromagnetic waves in the form of visible light. They use other kinds of telescopes to study the other forms of electromagnetic radiation—radio waves, infrared rays, ultraviolet rays, X rays, and gamma rays. One of their major techniques is the study of patterns of *wavelength* (distance between successive wave crests) of the radiation emitted by celestial objects. For example, analysis of the pattern of wavelengths in the light from a star provides information about the star's density and temperature. Harding E. Smith

Asturias, *ahs TOO ryahs,* **Miguel Angel,** *mee GEHL AHNG hehl* (1899-1974), a Guatemalan author and diplomat, won the Nobel Prize for literature in 1967. His early work *Legends of Guatemala* (1930) displays a creative use of Central American Indian traditions. His novel *Mr. President* (1946) condemns political dictatorship while experimenting with narrative techniques. His novel *Men of Corn* (1949) combines mythological narrative from Indian sources with social criticism. The trilogy of novels *Strong Wind* (1950), *The Green Pope* (1954), and *The Eyes of the Interred* (1960) focuses on unjust conditions of agricultural work in Central America.

Asturias was born in Guatemala City. He was his country's ambassador to France from 1966 to 1970.

Naomi Lindstrom

Asunción, *AH soon SYAWN* (pop. 500,938), is the capital, largest city, and chief port of Paraguay. It is in southern Paraguay on a bay of the Paraguay River. This river flows into the Paraná River. The two rivers link Asunción with the Atlantic Ocean, about 1,000 miles (1,600 kilometers) by water to the south. For the location of Asunción, see **Paraguay** (map).

Downtown Asunción is made up of rectangular blocks in which older, low buildings stand near modern skyscrapers. Treelined plazas provide relief from the busy streets.

The Pantheon of Heroes, which honors Paraguay's war heroes, faces the city's main plaza. Nearer the Paraguay River are the National Cathedral, the Government Palace, and Constitution Plaza. One of the few remaining buildings from the Spanish colonial period is the Casa de la Independencia, where Paraguayan nationalists plotted their freedom from Spanish rule in 1811. There are many buildings from the late 1800's and the early 1900's. The highly decorated Main Post Office dates from about 1900. The city also has a working system of electric trolleys dating from 1913.

Most Spanish-style houses in and around Asunción have been replaced by modern homes. The city has large slums. Most of Asunción's residents are of mixed Spanish and Indian ancestry. Many speak both Spanish and Guaraní, an Indian language.

The main industries in Asunción include the processing of agricultural and forest products for export; and the production of textiles, footwear, and food products. Most people work in these industries, in commerce, or for the national government.

Spanish colonizers founded Asunción in 1537. Asunción became the seat of government for all of Spain's territory in southeastern South America, and remained so until 1617. The city has been the capital of Paraguay since the nation gained independence from Spain in 1811. Nathan A. Haverstock

See also **Paraguay** (picture).

Aswan, *AS wahn* or *ahs WAHN* (pop. 220,000), is an important commercial, mining, and resort city in southeastern Egypt. It lies on the east bank of the Nile River, about 430 miles (692 kilometers) south of Cairo. For location, see **Egypt** (political map).

Aswan serves as a major market center for farmers of the Nile Valley traders from Sudan, and Arab nomads called *Bedouins*. The city also ranks as a leading transportation center. A principal line of Egypt's chief railroad extends from Aswan to Cairo. The Aswan High Dam, which has revolutionized the Egyptian economy, stands about 5 miles (8 kilometers) south of Aswan (see **Aswan High Dam**). Red granite mined near Aswan has been used to build many of Egypt's most famous monuments since ancient times. Aswan's hot, dry climate makes the city a popular health resort. For the monthly weather in Aswan, see **Egypt** (Climate). Robert L. Tignor

Aswan High Dam, *AS wahn* or *ahs WAHN,* controls the floodwaters of the Nile River in Egypt. It stands south of the city of Aswan, on the northern shore of Lake Nasser in southeastern Egypt. For location, see **Egypt** (political map). The dam measures 364 feet (111 meters) high and about $2\frac{1}{3}$ miles (3.7 kilometers) long.

The dam was designed to provide Egypt with a regular supply of water for irrigation the year around. To accomplish this goal, the dam holds back a vast quantity of water in Lake Nasser, which extends from the dam into Sudan. The water is used to irrigate farmland during dry periods and to generate electric power for factories and rural villages. The dam increased the amount of land irrigated the year around by about $2\frac{1}{4}$ million acres (910,000 hectares). It enabled Egypt to double its agricultural production.

The dam has seriously damaged the environment, in addition to providing benefits. For thousands of years, farmland along the Nile has been fertilized by *silt* (layers of earth particles) deposited by the floodwaters. Today, the dam prevents this water from flowing over the land, and so farmers must enrich the soil with expensive chemical fertilizers. The absence of silt has also increased the *erosion* (wearing away) of land along the Mediterranean coast near the Nile. In addition, the dam has caused poor drainage of nearby land.

Scientists also blame the dam for an increase of a disease called *schistosomiasis,* which causes intestinal and urinary infections. Schistosomiasis is transmitted by microscopic worms that breed in snails living in the Nile and its canals. The worms are discharged into the Nile and its canals, where they bore into the skin of people who wash clothes, bathe, or swim in the water. Before year-round irrigation became available, the snails died when the canals dried up. Today, however, the canals are full all year, enabling the snails to live and the disease to spread rapidly.

Construction of the dam began in 1960 and cost about $1 billion. The dam began operating in 1968. The Soviet Union provided technical assistance and more than $300 million in loans for the project. The dam replaced the smaller Aswan Dam, which stands nearby and is used chiefly to generate electric power. Robert L. Tignor

Asylum, in international law, is shelter and protection that is given by a nation to a person who is fleeing another nation. The granting of asylum is guided by national laws and international laws and treaties. According to the United Nations, refugees may seek asylum if they fear persecution based on race, religion, nationality, or social or political beliefs. But no person has a right to asylum. Political persecution is the main reason nations grant asylum.

The two main types of asylum are *territorial* and *nonterritorial.* Territorial asylum is granted within a nation's boundaries. Nonterritorial asylum, commonly called *diplomatic asylum,* is given in foreign diplomatic missions—such as embassies—and on ships. Under in-

ternational law, no nation may grant diplomatic asylum unless a treaty with the host nation allows for it. But even then, the practice is rare.

Asylum is an ancient practice. Early Israelite and Greek societies offered asylum for certain crimes. The ancient Romans recognized a more limited form of asylum. Political asylum started to flourish during the 1900's.

The United States bases its asylum policy on international law and the federal Refugee Act of 1980. In Canada, a federal agency dealing with refugees handles all requests for political asylum. Surya Prakash Sinha

AT&T Corp. is one of the world's largest communications companies. AT&T's business centers on providing voice, data, and video communications services to residential, business, and government customers throughout the world. The company manages the largest long-distance telephone network in the United States. AT&T also operates a cable television system. It offers local telephone service through its cable lines in some parts of the United States. In other areas, it offers local service through agreements with various local telephone companies. AT&T Corp. has headquarters in New York City.

AT&T was incorporated in 1885 as the American Telephone and Telegraph Company. It became commonly known as AT&T. The company eventually became the parent organization of what was sometimes known as the Bell System, which included AT&T and other subsidiary companies. Among these were 22 companies that provided local service to about 80 percent of U.S. telephone customers. In 1974, the U.S. government filed a lawsuit charging AT&T with anticompetitive practices. Settlement of the lawsuit resulted in the local companies being separated from AT&T in 1984. The company shortened its name to AT&T Corp. in 1994.

Prior to 1996, AT&T also produced communications equipment, such as telephones, telephone switching equipment, and computer chips. In 1996, AT&T divided its operations among three separate companies. Its communications services continued to operate under the AT&T name. NCR Corporation, a computer manufacturer AT&T had merged with in 1991, was separated from the company to operate the computer business. AT&T created a third company, Lucent Technologies Inc., to run its communications equipment business.

In 2000, the company that remained under the AT&T name announced a plan to further divide into four separate companies by 2002. The first of the new companies, AT&T Wireless, was spun off in 2001. It produces mobile telephones and provides wireless telephone service. The other new companies will be AT&T Business Services, which will provide long-distance calling and networking services to corporate customers; AT&T Consumer Services, which will provide long-distance calling service and Internet access to consumers; and AT&T Broadband, which will provide cable television service, Internet access via cable, and other high-speed communications. Critically reviewed by AT&T Corp.

Atacama Desert, *AT uh KAM uh* or *AH tah KAH mah,* is a barren, mineral-rich region in northern Chile and the southern tip of Peru. The desert begins near Tacna, Chile, and extends southward about 600 miles (970 kilometers). It is bordered on the west by the Pacific Ocean and on the east by the Andes Mountains. The Atacama Desert averages less than 0.5 inch (1.3 centimeters) of rain yearly. Its surface contains much sand and gravel. Beds of salt are scattered throughout. For location of the Atacama Desert, see **Chile** (terrain map).

The Atacama is the world's only source of natural sodium nitrate, a mineral used in making fertilizers and gunpowder. Until the 1920's, when the production of synthetic sodium nitrate began, the desert was the world's only producer of the mineral. The desert also yields copper, iron ore, lithium, and silver.

Chile defeated Bolivia and Peru in the War of the Pacific (1879-1883). As a result of its victory, Chile took possession of all parts of the Atacama Desert that had been controlled by Bolivia and Peru. In 1929, Chile returned the northern end of the desert to Peru. Robert C. Eidt

See also **Chile** (The Northern Desert; picture).

Atahualpa, *AH tah WAHL pah* (1500?-1533), also called Atabalipa, was the last ruler of the Inca Empire in Peru. In 1532, soon after he took the throne, Francisco Pizarro and his men landed in Peru (see **Pizarro, Francisco**). Atahualpa refused to recognize King Charles I of Spain as his overlord or to accept Christianity. Pizarro's men then killed over 4,000 unarmed Inca nobles and imprisoned Atahualpa in the city of Cajamarca. Although he had one room filled with gold and another room filled twice with silver in ransom, Atahualpa was not released. He was executed in 1533. See also **Inca** (History). Brian S. Bauer

Atatürk, *AT uh TURK* or *ah tah TURK,* **Kemal,** *keh MAHL* (1881-1938), was the founder and first president of the Republic of Turkey. He served as president from 1923 until his death. Under Atatürk's leadership, Turkey adopted sweeping political, economic, and social reforms. Atatürk helped create a parliamentary form of government in Turkey and adopted European law codes. His government founded new industries and banks, gave women the right to vote, and improved education. In addition, the Roman alphabet was introduced for the Turkish language.

Atatürk also ordered all Turks to choose family names. He was given the name *Atatürk,* meaning *father of the Turks,* by the Turkish National Assembly in 1935.

Mustafa Kemal was born March 12, 1881, in Thessaloniki, Greece (then part of the Ottoman Empire). He attended military schools. During World War I (1914-1918), he rose to the rank of general. He became famous for his role in defeating the Allies at Gallipoli Peninsula. After the war ended, he organized a Turkish nationalist movement and resisted Allied plans to break up Asia Minor. His forces drove Armenian, Greek, and French troops from the area, forcing the Allies to negotiate the Treaty of Lausanne and to recognize Turkish independence in 1923. Justin McCarthy

Ataxia, *uh TAK see uh,* is a lack of coordination in the muscles. It is a symptom of damage to part of the central nervous system. Ataxia involves a lack of balance, or equilibrium. Patients must stand on a broad base, eyes open, or they will sway or even fall. The swaying may increase if they shut their eyes.

Many diseases that damage the central nervous system may cause ataxia. They include tumors of the brain's cerebrum and cerebellum, some deficiency diseases, and diseases of the spinal cord. Ataxia may also result from overuse of such drugs as barbiturates or alcohol. In addition, ataxia may be due to syphilis, especially if

the patient's unsteadiness occurs or increases when the eyes are closed (see **Syphilis**). Marianne Schuelein

Atchison, David Rice (1807-1886), was a United States senator from Missouri. Some people claim that he was president of the United States for one day—March 4, 1849. This was to be Zachary Taylor's inauguration day. However, it was postponed one day because it fell on Sunday. Technically, there was no president that day. Atchison, as president *pro tempore* of the Senate, was next in line for the office. He was elected president *pro tempore* of the Senate 16 times between 1846 and 1854. He was born in Frogtown, Kentucky.

Robert F. Dalzell, Jr.

Athabasca, Lake. See Lake Athabasca.

Athabasca River, *ATH uh BAS kuh,* is one of the most important rivers in western Canada. It begins in the Rocky Mountains with water that melts from the Columbia Icefield and empties into Lake Athabasca (see **Alberta** [physical map]). The Athabasca River, which forms the southernmost part of the Mackenzie River system, is 765 miles (1,231 kilometers) long and flows entirely within Alberta. The river drains about 51,000 square miles (133,000 square kilometers) of land. Oil-soaked sands along the Athabasca, north of Fort McMurray, form one of the largest known oil deposits. The river was an important transportation route used by fur traders during the 1700's and 1800's. G. Peter Kershaw

Athanasius, *ath uh NAY shuhs,* **Saint** (295?-373), was the leading Christian churchman of his time. He gained importance for his many writings that defended orthodox Christianity against attacks by the Arians. The Arians were a religious sect who believed that only God the Father was completely divine. Athanasius also introduced Eastern Christian religious community life called *monasticism* to Western Christianity.

Athanasius was probably born in Alexandria. He was ordained a deacon about 318 by Bishop Alexander of Alexandria. In 325, Athanasius attended the Council of Nicaea, which helped establish the doctrines of orthodox Christianity. In 328, Alexander died and Athanasius succeeded him as bishop. Athanasius strongly defended the decrees of the council against Arianism. His defense of Nicaea cost him five different periods of exile. During one such period, he took refuge in the Egyptian desert. There, he wrote *Life of Anthony* (about 357), a biography of Saint Anthony of Thebes, the founder of Christian monasticism. This book influenced the establishment of monastic orders in the Western church. Athanasius's feast day is May 2. Marilyn J. Harran

Atheism, *AY thee ihz uhm,* is the belief that there is no God. Atheism is the opposite of *theism,* the belief that God exists. Atheism is also distinguished from *agnosticism,* a belief which states that human beings do not, and cannot, know whether any gods exist.

Atheists argue that God is never encountered in human experience. They believe that nothing in human experience needs to be explained by the existence of a deity. Atheists also reject the arguments that various thinkers have advanced to prove the existence of God.

Atheists point to the presence of serious imperfections in the world, such as widespread suffering and injustice. They argue that such imperfections show that the world could not have been created by a deity who was perfect in power and goodness. Atheism conflicts with most religions. However, some forms of Buddhism seem not to assert the existence of a supreme being.

Some prominent thinkers have been advocates of atheism. They include Baron Paul d'Holbach and Voltaire of France in the 1700's; Arthur Schopenhauer, Karl Marx, and Friedrich Nietzsche of Germany in the 1800's; and Bertrand Russell of England and Albert Camus and Jean-Paul Sartre of France in the 1900's. Ivan Soll

Athena, *uh THEE nuh,* in Greek mythology, was the goddess of warfare, wisdom, and arts and crafts. She also was the patron goddess of Athens. The Athenians called Athena *Parthenos* (Virgin) because of her chosen state of virginity. In the 400's B.C., they dedicated a temple called the *Parthenon* to Athena. Athena represented strategic war planning rather than the raw violence of war. The Romans identified their goddess Minerva with Athena.

Roman marble copy of a Greek sculpture (400's B.C.); Vatican Museums, Rome (SCALA/Art Resource)

Athena

According to some ancient sources, Athena was born full-grown and dressed in armor from the head of Zeus, the king of the gods. Zeus had swallowed the goddess Metis when Metis was pregnant with Athena. From her mother, Athena inherited cunning and, according to some sources, an ability to change shape and assume disguises. Athena also embodied the ancient Greek ideal of self-restraint. Athena assisted and inspired such Greek heroes as Heracles, Odysseus, and Perseus.

As the goddess of arts and crafts, Athena was skilled at weaving, embroidery, and spinning. According to one myth, a mortal woman named Arachne once boastfully challenged Athena to a weaving contest. After the contest, Athena turned Arachne into a spider so she would have to spend the rest of her life spinning.

Athena is depicted in art as a tall, stately woman wearing a crested helmet and carrying a spear and shield. On the shield was the head of Medusa, which could paralyze her foes (see **Medusa**). Athena is often shown accompanied by a snake and carrying an owl on her shoulder. Nancy Felson

The ruins of ancient Athens stand among modern buildings in the southwest part of the city. Remains of the Parthenon and other temples are on a hill called the Acropolis, *background.* Sixteen columns are all that is left of the Temple of Olympian Zeus, *foreground.*

Athens, *ATH ihnz* or *ATH uhnz* (pop. 748,110; met. area pop. 3,096,775), is one of the world's most famous and historic cities. It became the capital of Greece in 1833, after the Greeks freed themselves from Ottoman rule. But Athens's greatest fame dates from the 400's B.C., when it was the world's most powerful and most highly civilized city. The city's name in Greek is *Athinai.*

Athens lies on a plain near the southern end of Attica, a peninsula that extends from southeastern Greece into the Aegean Sea. A crescent of mountains up to 4,600 feet (1,400 meters) high bounds Athens on the west, north, and east. Athens is about 5 miles (8 kilometers) from Piraeus, Greece's largest seaport.

When Greece gained independence in 1829, Athens had only a few thousand people. The city evolved dramatically during the reign of Otto I, a Bavarian prince who became the first ruler of the new Greek kingdom. Otto was king of Greece from 1832 to 1862. Under his direction, German architects planned and built modern Athens.

Ancient Athens was the leading cultural center of the Greek world. Many of the most gifted writers of Greece lived there. They wrote works of drama, history, lyric poetry, and philosophy that have influenced literature for centuries. Athenian architects built masterpieces of classical beauty, and the ruins of many of these structures may still be seen. The government of ancient Athens provided an example of democracy that has inspired lawmakers ever since. The ancient Athenian statesman Pericles called Athens the "school of Greece." In many ways, the city was the birthplace of Western civilization.

John J. Baxevanis, the contributor of this article, is Dean of the Faculty of Social Sciences at East Stroudsburg University and the author of Economy and Population Movements in the Peloponnesos of Greece.

The modern city

Landmarks. The bustling life of modern Athens centers around the city's three main squares—Syntagma, Omonoia, and Monastiraki. Syntagma Square, or Constitution Square, is the administrative center of Athens. The Parliament Building, formerly the royal palace, faces Syntagma. In 1843, the new Greek Constitution was proclaimed from the balcony of this building. A special corps of Greek soldiers, called *evzones,* guards the Tomb of the Unknown Soldier and the Parliament Building. The evzones wear a colorful traditional uniform including a red tasseled cap, embroidered vest, white kilt, and red leather slippers. Hotels and office buildings also face Syntagma.

Omonoia Square, also known as Concord Square, lies about $\frac{1}{2}$ mile (0.8 kilometer) northwest of Syntagma. The area between Omonoia Square and Syntagma Square is Athens's chief shopping center. Omonoia Square has numerous department stores, restaurants, and other businesses. Main streets and trolley lines branch out from Omonoia.

South of Omonoia lies Monastiraki Square, the heart

of an old market district. Numerous small shops, open-air stalls, and street vendors surround Monastiraki. To the southeast is the Plaka, a district that dates from the time when Turkey controlled Greece. The Plaka still shows Turkish influence in its winding, cobblestoned alleys. But today it also hosts many nightclubs and hotels.

In northeastern Athens, the cone-shaped hill of Lycabettus rises steeply to a height of about 910 feet (277 meters). It offers a dramatic view of the city. Directly south of Lycabettus lies the fashionable residential district of Kolonaki. The large, flat hill of the Acropolis, to the southwest, was the original center of life in ancient Athens. Here lie the remains of the Erechtheum, the Parthenon, the Propylaea, the Temple of Athena Nike, and other reminders of the glorious past.

People. Athens ranks as the cultural center of Greece, and large numbers of foreigners live in the city or visit there. As a result, Athens has an international atmosphere and a more modern style of life than any other Greek city.

The great majority of Athenians, like more than 95 percent of all Greeks, belong to the Greek Orthodox Church. Athens has many churches. The largest is the Cathedral, begun in 1840 and completed in 1855. The church of Saint Nicodemus dates from the early 1000's.

Athenian food is similar to food served in other eastern Mediterranean regions. The people of Athens eat lamb prepared in many different ways, as well as a wide variety of fish and other seafood. Other popular Greek specialties include *feta,* a cheese made from sheep's or goat's milk, and *retsina,* a wine flavored with pine resin.

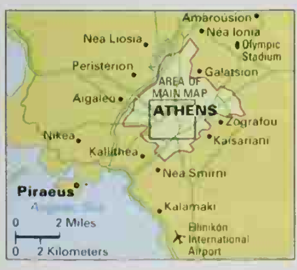
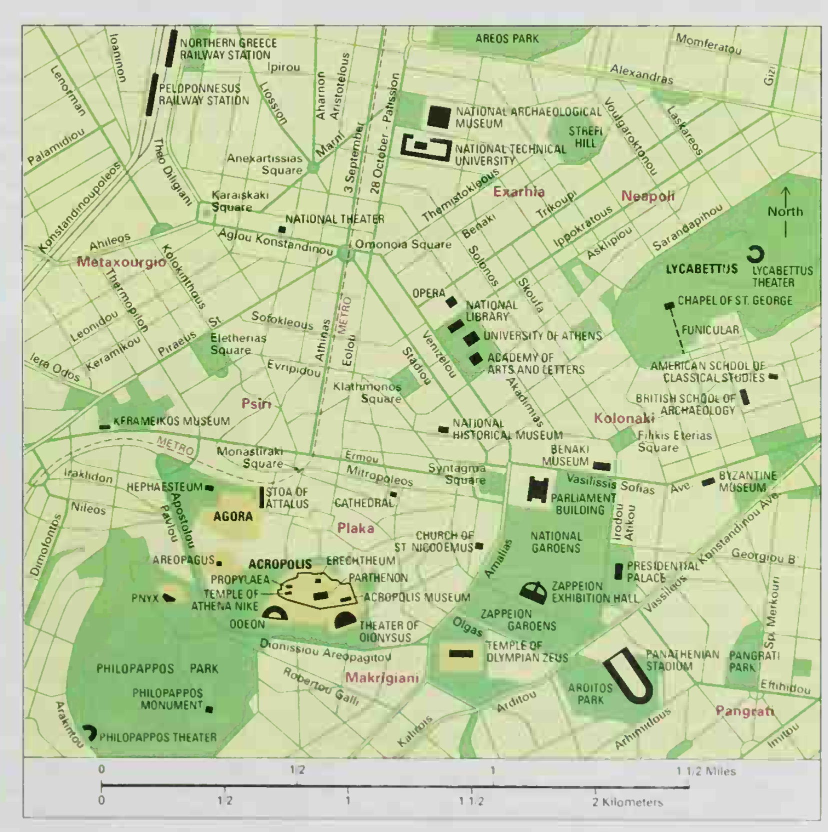
The Parliament Building is the center of the Greek government. It faces Syntagma Square, the administrative center of modern Athens. The building once served as the royal palace.

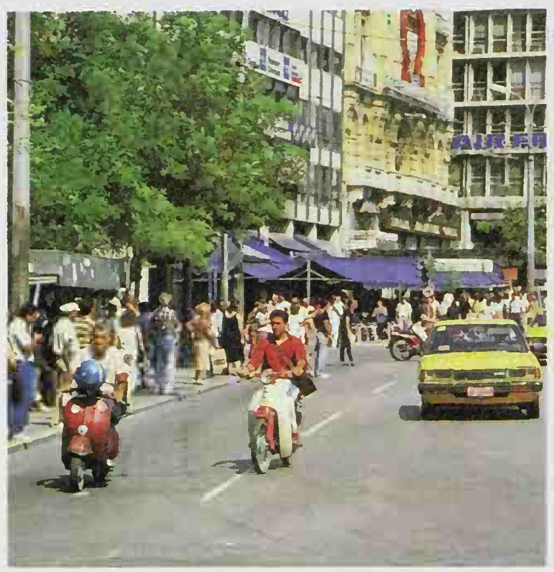


Most Athenians live in small apartments or inexpensive houses. Many of the people own an automobile, but most of them ride the city's buses and trolleys or the subway that connects Athens with Piraeus.



Education and cultural life. Athens has many public schools and several institutions of higher learning. The University of Athens, founded in 1837, has schools of law, medicine, philosophy, theology, and mathematics and the physical sciences. At the National Technical University of Athens, students study engineering and other subjects not taught at the University of Athens.

Athens



WORLD BOOK maps

© Margot Granitsas, The Image Works

Downtown Athens is a busy center of shops, offices, and hotels. Many tourists visit Athens, the cultural center of Greece, and large numbers of foreigners live and work there.

Next door to the National Technical University stands the National Archaeological Museum, one of the world's greatest museums. It houses masterpieces of jewelry, pottery, and sculpture from all areas and every period of ancient Greece. Other museums in Athens include the Benaki Museum, which features art objects from medieval and modern Greece; the Acropolis Museum; and the Byzantine Museum.

The city's archaeological schools have won worldwide fame, especially the American School of Classical Studies at Athens and the British School of Archaeology in Athens. These two schools, founded in the 1880's, conduct excavations and train archaeologists.

Economy. Athens is the economic and financial center of Greece. It is the headquarters for the nation's major corporations, including insurance companies and research institutions. Tourism is the single largest source of income for the city, which hosts more than 7 million visitors each year. Goods manufactured in the metropolitan area include chemicals, clothing, electronic equipment, food products, machinery, medicines, military supplies, petroleum products, pharmaceuticals, ships, and textiles. The city also produces brassware, jewelry, and a wide variety of other items popular with tourists.

The ancient city

The Acropolis and its buildings. The ancient Greeks built Athens upon and around a great flat-topped, rocky hill. This hill, which covers a little more than 10 acres (4 hectares), became known as the Acropolis. The Greek words *akro* and *polis* mean *high city,* and the early rulers of Athens probably lived on the steep, easily defended hill. Through the years, the Athenians built temples and public buildings on the Acropolis, and people stopped living there.

By about 1200 B.C., the Athenians had erected a wall around most of the Acropolis. Parts of the wall still stand, but a series of larger walls replaced it during the 400's B.C. About 530 B.C., the Athenians built a temple on the Acropolis and dedicated it to Athena, the patron goddess of the city. The temple was Athens's largest building until 480 B.C. That year, a Persian army captured the city and destroyed most of the buildings on the Acropolis. In 447 B.C., the people of Athens began to rebuild the Acropolis site under the leadership of the great statesman Pericles. They erected many new structures, including the magnificent Parthenon, a marble temple dedicated to Athena (see **Parthenon**).

Pericles also began the Propylaea, the huge monumental entrance to the Acropolis. In 431 B.C., the Peloponnesian War interrupted its construction, and the Propylaea was never completed. To its right stands the small temple of Athena Nike. The Erechtheum, a temple built in several joining sections, stands about 60 yards (55 meters) from the Parthenon. It was completed about 400 B.C. The Athenians dedicated it to Athena, the god Poseidon, and Erechtheus, a legendary king of early Athens. The most famous part of the Erechtheum is the south porch, where six columns in the form of standing maidens hold up the roof. Cement copies have replaced the original marble figures. Most of the original figures were moved to the Acropolis Museum in the early 1980's for protection from air pollution.

Other buildings. Southeast of the Acropolis stands the Theater of Dionysus, where the playwrights of ancient Athens staged their dramas. The surviving structure dates from the 300's B.C., but it includes many changes made in later times. The theater could seat about 15,000 spectators. Southwest of the Acropolis stands the restored Odeon, a theater that seats more than 5,000 people. It is still used for plays and concerts (see **Europe** [picture: Ancient Greek drama]). Herodes Atticus, a wealthy Greek, built the Odeon about A.D. 160.

The Temple of Olympian Zeus, the largest temple ever built in Greece, stood about 400 yards (370 meters) east of the Theater of Dionysus. The Athenian tyrant Pisistratus began the structure about 530 B.C., but many interruptions delayed it. The temple was finally completed during the reign of the Roman emperor Hadrian, who ruled from A.D. 117 to 138. The building had 104 col-

The National Archaeological Museum is one of the world's greatest museums. Its exhibits include jewelry, pottery, and sculpture from every period of ancient Greek civilization.

umns, each 56 feet (17 meters) high, but only 16 remain.

Northwest of the Acropolis was the Agora, the marketplace of ancient Athens. Archaeologists have uncovered the ruins of many of the Agora's public buildings. Along the east side of the Agora stood the Stoa of Attalus, a long, roofed *colonnade* (row of marble columns) that housed many shops. It was built between 159 B.C. and 138 B.C. and was restored in the A.D. 1950's. Today the Stoa of Attalus serves as a museum and as headquarters for excavations of the Agora. See **Greece, Ancient** (illustration: A bustling marketplace). Just outside the Agora stands the Temple of Hephaestus (also called the Hephaesteum or Theseum), built about 449 B.C. It remains the best-preserved temple in Greece.

History

Earliest times. Scholars know little about the history of Athens before about 1900 B.C., when Greeks first occupied Attica. Later invaders never drove out the Greek settlers, as they did in other parts of Greece.

Athens was one of the first *city-states.* Each of these independent states consisted of a city and the region that surrounded it. Athens had a king, as did other Greek states. According to tradition, the first king of Athens was named Cecrops. Kings ruled the city-state until 682 B.C. Beginning that year, elected officials called *archons* headed the government of Athens. The general assembly, which consisted of all adult male citizens of Athens, elected the archons to one-year terms. At first, a group of three archons managed the affairs of Athens. In time, the people increased the group to nine.

After their term of office, the archons joined the Areopagus, a council of elder statesmen. The Areopagus judged murder trials and prepared political matters for the vote of the general assembly. See **Areopagus**.

As Athens's population grew, the farmers of Attica could not produce enough food for all the people and for themselves. The ruling aristocracy gradually acquired the best farmlands. Many small farmers went into debt and borrowed food that they promised to pay back out of the next year's crop. Some, who could not pay their debts, even lost their land and became slaves. Civil war threatened to break out between the lower classes and the wealthy Athenians.

Solon, one of the archons of 594 B.C., made several important reforms. First he canceled all debts, thus freeing the people who had fallen into slavery. But they did not get their land back. Solon also set up qualifications for public office based on wealth. Any qualified citizen could become a public official, regardless of whether he belonged to the traditional ruling class. In addition, Solon reorganized and published all the laws of Athens.

Solon's work did not solve the problem of poverty in Attica. In 560 B.C., Pisistratus, a respected army commander, seized power and made himself tyrant (see **Tyranny**). He fell from power twice but ruled firmly from about 545 B.C. until his death in 527 B.C. The lower classes supported Pisistratus, and he repaid his followers by distributing land taken from his wealthy opponents. He thus continued the work of Solon in sharply reducing the power of the traditional ruling class. Pisistratus controlled, but did not suspend, the regular government and the archons. He made himself popular by making various improvements in the city, including construction of the first stages of the Temple to Zeus. After Pisistratus's death, his son Hippias ruled as tyrant.

Democracy. Hippias fell from power in 510 B.C., and Cleisthenes, the head of a leading family, became the most powerful statesman in Athens. About 508 B.C., the Athenians adopted a new constitution proposed by Cleisthenes, which made the state a democracy. This constitution was an unwritten one, but it stayed in effect with little change for hundreds of years. The constitution kept the ideas of Solon, but it also provided for new conditions that had developed since Solon's rule.

Until Cleisthenes's time, citizenship had been based on blood relationship to the four Ionic tribes that had originally settled Attica. A man had to belong to a *phratry* (brotherhood) to be a citizen. Under Cleisthenes's system, all men 18 years of age and older were registered as citizens and as members of the *deme* (village or town) in which they lived. In time, membership in the demes became hereditary, and so a man might belong to a deme in which he did not actually live. Cleisthenes organized the demes into 30 groups called *trittyes,* which, in turn, were grouped into 10 new tribes. Each of the 10 tribes was made up of 3 trittyes from different regions of Athens. Thus, members of each tribe came from various families and different parts of the city-state.

Cleisthenes's most important reform was the creation of a council of 500 members who were chosen each year by drawing lots. The council prepared business for the general assembly. The new political system provided every citizen of Athens with a chance to help run the city government. All citizens were eligible for the council and for other offices. Women were not considered citizens and could not vote or hold office. In time, all public officials except generals were chosen annually by drawing lots. Generals were elected. Individuals who were considered to be a threat to the government could be banished for 10 years by a vote of the people.

The Golden Age. Athens played a leading role in the Greek victories over Persia in the two Persian Wars (490 B.C. and 480-479 B.C.). Athens soon became head of the Delian League, a group of Greek states organized to continue to wage war against Persia. The league quickly developed into an Athenian empire. The period from 477 to 431 B.C., called the Golden Age, was the most brilliant in Athenian history. During this time, Athens was led by the great statesman Pericles. He increased Athens's power in Greece and reformed its government. Pericles also funded many great works of art and architecture. Athens became famous as the literary and artistic center of Greece.

War and decline. Athens led the empire into the Peloponnesian War (431-404 B.C.) against Sparta and its allies. Sparta won the war and remained the most powerful Greek state until 371 B.C., when Thebes defeated it.

Although Athens never regained its political leadership, it remained Greece's intellectual center. People came to Athens as a center of culture under Macedonian rule, and later under Roman rule. For hundreds of years, wealthy Romans sent their sons to Athens to complete their education. However, Athens lost its position as a cultural center in A.D. 529, when the Byzantine emperor Justinian closed the city's schools of philosophy.

From about 1100 to 1400, during the Middle Ages, Athens declined even further. As the power of Byzan-

tium weakened, various Italian and other European rulers occupied the neglected city. In 1456, Athens fell to the Ottoman Empire. The Islamic Ottomans did little to restore the Christian city to its former glory.

In 1833, after the Greek War of Independence, Athens became the capital of the new kingdom of Greece. The first king, Otto I, and his advisers were German. They applied modern Western European designs—such as public squares and straight streets—to the urban landscape along the northern and eastern slopes of the Acropolis. The population grew to about 500,000 by the mid-1920's.

During World War II (1939-1945), Athens was an *open city*—that is, the Greeks agreed to neither fortify nor defend Athens. They made this agreement to protect the city's historic buildings and works of art against bomb attacks. However, it did nothing to protect Athenians from harsh treatment at the hands of the Germans, who occupied Athens in April 1941. The following winter, thousands of Athenians died of starvation. German troops abandoned the city in 1944.

Renewal. After the war, archaeologists again began to restore the ruins of ancient Athens. New buildings began to replace structures that had been erected during the reign of Otto I in the mid-1800's. The historic skyline of three-story buildings is now dotted with modern skyscrapers. In the 1990's and early 2000's, new construction continued as Athens prepared to host the 2004 Olympic Games. John J. Baxevanis

Atherosclerosis. See Arteriosclerosis.

Athlete's foot is an infectious skin disease that involves itching and scaling between the toes and on the soles of the feet. It is caused by a type of microscopic fungus. Nearly everyone comes into contact with this fungus, but some people are infected easier than others. The fungi thrive on warm, moist skin surfaces. For this reason, the disease affects many athletes and other people whose feet regularly become hot and sweaty.

Athlete's foot starts between the toes and then makes the bottoms of the feet red and scaly. In some cases, it also causes blisters. The disease may spread to other parts of the body. It is then known as *ringworm* (see **Ringworm**). Athlete's foot is sometimes also called *ringworm of the feet*.

The disease is treated by—and can be prevented by—washing and drying the feet thoroughly; wearing socks and shoes that provide proper ventilation; using talcum powder to absorb the moisture; and, if needed, applying medicine that kills the fungus. The fungus is hard to get rid of completely if the toenails become infected. Repeated attacks of athlete's foot may occur in such cases. In severe or long-lasting cases, a physician may prescribe a drug called *griseofulvin*. Yelva Liptzin Lynfield

Athletics means sports in the United States (see **Sports**). In the United Kingdom and Commonwealth countries, it refers to track and field events (see **Track and field**).

Athlone, Earl of (1874-1957), a member of the British royal family and a military officer, served as governor general of Canada from 1940 to 1946. As governor general, he devoted himself to maintaining the Canadian war effort in World War II (1939-1945). In 1943 and 1944, he hosted President Franklin D. Roosevelt of the United States and Prime Minister Winston Churchill of the United Kingdom during two historic wartime conferences at his residence in Quebec.

The Earl of Athlone was born on April 14, 1874, in London. His full name was Alexander Augustus Frederick William Alfred George Cambridge. He was the younger brother of Queen Mary, wife of King George V. In 1904, he married Princess Alice, a granddaughter of Queen Victoria. He was an officer in the British Army and served in the Second Anglo-Boer War (1899-1902) and World War I (1914-1918). He became Earl of Athlone in 1917. From 1923 until 1930, the earl was governor general of South Africa. Jacques Monet

Atkins, Chet (1924-2001), was one of the most influential individuals in the development of modern country music in the United States. Atkins helped shape country music as a guitarist, record producer, and recording company executive. Atkins is credited with being a major force behind the creation of the "Nashville sound," which broadened the audience for country music internationally in the late 1950's and 1960's.

Chester Burton Atkins was born on June 20, 1924, near Luttrell, Tennessee. As a young guitarist, he greatly admired the playing of Merle Travis, who he heard on the radio. Travis played rhythm on the lower strings with his thumb, while playing melody on the higher strings with his index finger. Atkins developed the style further, often using two or even three fingers instead of one. Atkins toured with country bands and played on various radio shows during the 1940's. He first performed at the Grand Ole Opry in Nashville in 1946. Atkins settled permanently in Nashville in 1950.

Atkins made his first solo recording in 1946 and recorded over 100 albums. He served as vice president of Nashville operations for RCA Victor Records from 1968 to 1982. During those years, he helped shape the Nashville sound, which brought a smooth, pop-oriented style to country music. Paul F. Wells

Atlanta Convention and Visitors Bureau

Atlanta's skyline has many prominent buildings. The three tallest pictured here are, *left to right,* the stair-shaped Georgia Pacific Building, 191 Peachtree, and the Westin Peachtree Plaza.

Atlanta

Atlanta is the capital and largest city of Georgia. It serves as a center of trade and transportation for the Southeastern United States. More than 400,000 people live in the city, and the Atlanta metropolitan area has about 4 million people.

Atlanta is known for its rolling hills and beautiful dogwood blossoms. It lies in northern Georgia, in the foothills of the Blue Ridge Mountains.

In 1837, a town called Terminus was founded at what is now Atlanta. The town soon developed into a busy trade and transportation center. In 1845, it was renamed Atlanta. During the Civil War (1861-1865), Atlanta served as a Confederate supply depot. Union troops led by General William T. Sherman captured the city in 1864 and burned most of its buildings.

Atlanta has had several periods of industrial expansion and construction growth. Today, it is the center of one of the fastest-growing U.S. urban areas.

The city

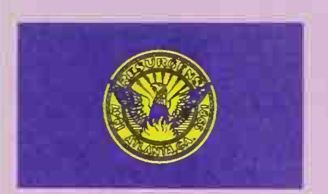
Layout of Atlanta. Atlanta covers 132 square miles (342 square kilometers). The Chattahoochee, one of Georgia's major rivers, forms part of the city's western border. Most of Atlanta lies in Fulton County, but its easternmost section extends into DeKalb County.

Downtown Atlanta is a bustling area in the east-central part of the city. It has a mix of modern office towers and mid-rise buildings that date from the late 1800's and early 1900's. The traditional heart of downtown is an intersection called Five Points, which has a cluster of banks, department stores, and office buildings. To the east is Auburn Avenue, the location of the Martin Luther King, Jr., National Historic Site. The site honors King, who was born in Atlanta and became a famous civil rights leader. It includes King's birthplace; the Ebenezer Baptist Church, where King preached; and the King Center, which houses his tomb. The State Capitol—which dates from 1889—and other government buildings stand near Five Points. Underground Atlanta, a 22-acre (9-hectare) shopping and entertainment complex lies below street level just south of Five Points.

Atlanta's most famous street, Peachtree, runs from downtown northward to residential areas. It is the site of Peachtree Center, a modern downtown business complex that includes hotels, office buildings, restaurants, shops, and convention and entertainment facilities. Also to the north of downtown is Atlanta's tallest building, the 1,023-foot (312-meter) Bank of America Plaza. Other landmarks include the cylinder-shaped Westin Peachtree Plaza, which is the tallest hotel in the Western Hemisphere; and the Fox Theater, a grand movie house that dates from 1929.

Residential areas spread out beyond the downtown region. Industrial activity is scattered throughout the area, most heavily in the south.

The metropolitan area. Atlanta's metropolitan area spreads out over 20 counties and covers 6,126 square



Facts in brief

Population: *City*—416,474. *Metropolitan area*—4,112,198.
Area: *City*—132 mi^2 (342 km^2). *Metropolitan area*—6,126 mi^2 (15,866 km^2), excluding inland water.
Altitude: 1,050 ft (320 m) above sea level.
Climate: *Average temperature*—January, 41 °F (5 °C); July, 79 °F (26 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—51 in (130 cm). For the monthly weather in Atlanta, see **Georgia** (Climate).
Government: Mayor-council. *Terms*—Four years for the mayor, the council president, and the 18 council members.
Founded: 1837. Incorporated as a city, 1847.

Largest communities in the Atlanta area

Name	Population	Name	Population

Symbols of Atlanta. The flag, *left,* and the seal, *right,* feature the phoenix and the dates 1847 and 1865. Atlanta was chartered as a city in 1847. Atlanta adopted the phoenix as a symbol because, like that bird of Greek mythology, the city rose from its own ashes. Rebuilding began in 1865.

Atlanta Convention and Visitors Bureau

The tomb of Martin Luther King, Jr., stands at the Martin Luther King, Jr., National Historic Site in Atlanta. The civil rights leader was a minister in Atlanta, his hometown.

Atlanta Convention and Visitors Bureau

Underground Atlanta is a shopping and entertainment complex that lies beneath street level in the heart of downtown. The mall spans 22 acres (9 hectares) and is mostly enclosed.

miles (15,866 square kilometers). It is home of about half of Georgia's people.

Most of the metropolitan area population is concentrated in five counties—Clayton, Cobb, DeKalb, Fulton, and Gwinnett. Sandy Springs, Atlanta's largest suburb, lies north of the city. Other large suburbs include East Point, Marietta, Roswell, and Smyrna.

Atlanta's suburban areas offer many historical sites as well as new housing developments and large business districts. At least two business complexes rival those within the city limits and are anchored by major shopping malls. The malls are Cumberland Mall/Galleria Mall in Cobb County and Perimeter Mall in DeKalb County. The metropolitan area also offers beautiful scenery the year around. Popular recreation areas near Atlanta include the Blue Ridge Mountains and Lake Sidney Lanier, both north of the city.

People

Ethnic groups. African Americans make up Atlanta's largest single ethnic group. They account for about 61 percent of the city's population. In the entire metropolitan area, whites make up about 63 percent of the population and African Americans about 29 percent. The largest white groups include people of British, German, and Irish ancestry. Asians and Hispanics represent small but growing parts of the area's population.

Housing. Atlanta is famous for its large, single-family houses with beautiful flower gardens and dogwood blossoms. The Druid Hills area is one of the nation's oldest planned suburban neighborhoods. It was designed in 1903 by American landscape architect Frederick Law Olmsted and Atlanta businessman Joel Hurt. The neighborhood is known for its large houses, broad front lawns, and curving streets shaded by towering trees. Other suburbs also include luxurious neighborhoods.

Substandard housing is a problem in some older neighborhoods in poor areas of the central city, especially those south of downtown. A number of private organizations, including Georgia-based Habitat for

City of Atlanta

Atlanta lies in northwestern Georgia. The larger map shows the city and some of its points of interest. The smaller map shows the Atlanta area.

WORLD BOOK maps

Humanity, run programs to assist in renovating or building houses for the poor.

Education. The Atlanta metropolitan area has about 700 public schools that serve about 500,000 students. The largest school systems are those of DeKalb and Cobb counties. About 36,000 students attend approximately 185 church-supported and other private schools in the Atlanta area.

Atlanta has about 35 accredited colleges and universities. The largest are Georgia State University and the Georgia Institute of Technology, often called Georgia Tech. The Atlanta University Center is the largest complex of predominantly African American colleges and universities in the United States. It consists of Clark Atlanta University; Morehouse, Morris Brown, and Spelman colleges; and the Interdenominational Theological Center. Located just outside the city limits, Emory University is recognized for its medical research programs. Other institutions of higher learning in the area include Agnes Scott College and Columbia Theological Seminary in Decatur, Kennesaw State University in Kennesaw, and West Georgia College in Carrollton.

Social problems. Atlanta faces many social problems experienced by other large urban areas. Major problems include crime and homelessness. Much of the crime is associated with the problems of drug abuse and gang activity. Rising housing costs have contributed to homelessness. In 1991, Georgia native and former U.S. President Jimmy Carter launched the Atlanta Project. The project is an effort to attack social problems in the poorest parts of the Atlanta area. Its volunteers work with community groups, churches, and local, state, and federal government programs to help the poor.

Cultural life

The arts. The Atlanta Ballet, founded in 1929, is the oldest regional ballet company in the United States. It performs in the Atlanta Civic Center. The Civic Center also hosts summer musicals produced by Theater of the Stars. The Robert W. Woodruff Arts Center houses the Alliance Theater Company, the Atlanta Symphony, and the Atlanta College of Art. Clayton State College in Morrow offers performances by the Thamyris chamber music ensemble at Spivey Hall. Suburban playhouses include the Neighborhood Playhouse in Decatur and the Theater in the Square in Marietta.

Museums and libraries. Collections at the High Museum of Art emphasize European and American paint-

ings and sculptures from the 1800's and 1900's. The museum is part of the Robert W. Woodruff Arts Center. Other art museums in Atlanta include the Hammonds House Galleries and Resource Center for African-American Art and the Michael C. Carlos Museum at Emory University. Atlanta's public library system has a downtown facility and about 25 branches.

The Atlanta Historical Society complex houses a museum and a library of local history. The Fernbank Science Center includes a planetarium and a forest preserve. Wren's Nest, the home of journalist Joel Chandler Harris, is now a museum. Harris is famous for his "Uncle Remus" stories, which were published during the late 1800's.

The Carter Presidential Center stands on a hill overlooking downtown Atlanta. This large complex houses the Jimmy Carter Library and the Carter Center of Emory University. The library contains items associated with Carter's term as president of the United States. The Carter Center of Emory University is a research institute that deals with international affairs.

Recreation. The Atlanta area has hundreds of parks. Piedmont Park, which opened in 1895, hosts the Atlanta Arts Festival each fall. The festival features art exhibits, concerts, and dance programs. A series of roadside parks near suburban North Druid Hills was designed by Frederick Law Olmsted. Grant Park includes the Atlanta Zoo and the Cyclorama, a circular painting of the Battle of Atlanta of 1864. The Cyclorama, housed around a moving platform, measures 42 feet (13 meters) high and 358 feet (109 meters) in circumference.

Atlanta has a number of professional sports teams. The city is the home of the Atlanta Falcons of the National Football League, the Atlanta Braves baseball team of the National League, the Atlanta Hawks of the National Basketball Association, and the Atlanta Thrashers of the National Hockey League.

Economy

The Atlanta metropolitan area is a center for service industries. It ranks as a leader in wholesale and retail trade, transportation, and communication. Service-related jobs employ about 447,000 of the area's people. Manufacturing employs about 195,000 people.

Service industries. Atlanta has a thriving wholesale trade industry. Much of this trade takes place in the huge downtown Merchandise Mart. Numerous large retail trade centers serve both residents of Atlanta and visitors.

Atlanta is a transportation and communication hub. Hartsfield International Airport in College Park ranks among the world's busiest airports for passenger and cargo flights. Delta Air Lines is headquartered in Atlanta. The city is also the chief railroad center of the Southeast. United Parcel Service, Inc., the largest U.S. package delivery company, has its headquarters in Atlanta. Two major communications companies headquartered in Atlanta are the Cable News Network (CNN) and BellSouth. A number of daily newspapers serve the area. The major paper is *The Atlanta Journal-Constitution.*

Government services also contribute to Atlanta's economy. The Georgia state government, based in Atlanta, employs many people. A number of federal government agencies also have offices in the area. The U.S. Centers for Disease Control and Prevention (CDC) maintains its headquarters just outside the city limits and has many laboratories in Atlanta. Military installations in the area include Fort McPherson south of downtown, Fort Gillem near Forest Park, and the Atlanta Naval Air Station and Dobbins Air Force Base near Marietta.

Atlanta Convention and Visitors Bureau

The Atlanta Arts Festival attracts many visitors with its varied art exhibits, concerts, and dance programs. Piedmont Park, which opened in 1895, hosts the festival each fall.

Manufacturing. The chief manufactured products of the Atlanta area include food, transportation equipment, tobacco products, electronics, and textiles. The Coca-Cola Company has its headquarters in Atlanta. Lockheed Martin Aeronautical Systems, which manufactures military planes, is near Marietta.

Government

Atlanta has a mayor-council form of government. The city's voters elect the mayor, the city council president,

Atlanta Convention and Visitors Bureau

The Coca-Cola Company maintains headquarters and a visitors' center in Atlanta. The brightly colored visitors' center, *shown here,* stands next to the company's executive offices.

and the 18 members of the council to four-year terms. The Atlanta area has over 60 other local government bodies, including county and city governments, local boards of education, and a regional transit authority.

History

Early days. The Creek Indians inhabited the Atlanta area before whites reached the region. In 1813, the U.S. Army sent troops commanded by Lieutenant George R. Gilmer to the area to build a fort about 7 miles (11 kilometers) northwest of present-day downtown Atlanta. The fort stood along the Chattahoochee River at a site known as Standing Peachtree. It became an important trading post. In 1837, the Western and Atlantic Railroad selected a site at what is now Atlanta for the end of a new rail line. A town called Terminus was established at the site. It was renamed Marthasville in 1843. In 1845, the town sought a new name. J. Edgar Thompson, a railroad engineer, suggested the name *Atlanta.* Some people say the name is a feminine version of *Atlantic* from the Western and Atlantic Railroad. Others say it is a feminine version of *Atlantis,* a legendary lost continent.

Destruction and redevelopment. Atlanta was chartered as a city in 1847. Fulton County was established in 1853, with Atlanta as the county seat. After the American Civil War began in 1861, Atlanta's central location and its railroad network made it a main shipping point for Confederate supplies. In 1864, Union troops led by General William T. Sherman captured Atlanta and burned most of it to the ground. Fewer than 400 of the city's approximately 3,700 buildings were left standing.

After the Civil War ended in 1865, Atlanta was quickly rebuilt. It replaced Milledgeville as the state capital in 1868. By 1880, Atlanta had over 37,000 residents and ranked as Georgia's largest city. In 1881, it held the International Cotton Exposition to focus attention on its potential as a manufacturing center. The city's Cotton States and International Exposition of 1895 included an exhibit on the progress made by blacks since the Civil War. The popular soft drink Coca-Cola was invented in Atlanta in 1886. By 1900, Atlanta had become an important manufacturing and retailing center and had nearly 90,000 residents.

In 1906, a race riot between blacks and whites resulted in 12 deaths and numerous injuries. Afterward, city leaders established a committee to promote racial tolerance. The riot resulted in black businesses moving away from the central business district to Auburn Avenue. Auburn Avenue gradually became an important street for black businesses and black churches.

Gate City of the South. In 1917, a fire destroyed about 2,000 buildings in Atlanta. The city was again quickly rebuilt. By 1920, Atlanta's 14 rail lines and 4 major railroads earned it the name *Gate City of the South.* Through a promotional campaign, the Atlanta area attracted hundreds of new businesses. In 1936, the nation's first federally funded low-income housing project, Techwood Homes, was opened in Atlanta.

The mid-1900's. World War II brought new military installations and industries to Atlanta. In 1943, the area's first naval air station opened on the site of what is now DeKalb-Peachtree Airport, near Chamblee. Many farmworkers moved to the Atlanta area to work in war industries and remained after the war ended in 1945. By 1950, about 330,000 people lived in the city, and the metropolitan area had grown to about 727,000. In 1952, Atlanta annexed 81 square miles (210 square kilometers) of suburban land to the north, west, and south of the city, adding about 100,000 residents to its population.

The 1960's marked a period of major growth for Atlanta. The area's first expressways were completed in the late 1950's and early 1960's. Atlanta-Fulton County Stadium, finished in 1965, became the home of the city's first major league sports team, the Braves.

In the 1960's, Atlanta became known as one of the South's most racially progressive cities. It was a center of leadership for the civil rights movement. Martin Luther King, Jr., and others founded the Southern Christian Leadership Conference (SCLC) in Atlanta in 1957 to coordinate the work of civil rights groups. Under Mayor Ivan Allen, Jr., who held office from 1962 to 1969, Atlanta integrated its public schools peacefully. An alliance of white business leaders and influential members of the black community helped accomplish this change. In 1969, city voters elected Sam Massell, Jr., a white, as mayor, and Maynard Jackson, a black, as vice mayor. Jackson was elected mayor in 1973. He became the first black mayor of a major Southern city. He was reelected in 1977.

The late 1900's. Andrew Young, also a black, was elected to succeed Jackson in 1981 and was reelected in 1985. Jackson was elected mayor again in 1989. In 1993, Bill Campbell, another black, was elected to succeed Jackson. He won reelection in 1997.

Atlanta's population reached its highest level, about 495,000, in 1970. In the next 20 years, the movement of many Atlantans to the suburbs helped cause the city's population to decrease to about 394,000. But the move to the suburbs and an increase of the size of the metropolitan area helped the metropolitan population soar from about 1,600,000 in 1970 to about 4 million in 2000.

The Omni International Complex, a recreational and commercial center, opened in 1975. In 1986, Atlanta businessman Ted Turner bought the complex and renamed it the CNN Center after his Cable News Network (CNN). The Georgia World Congress Center, a state-owned convention center, was completed in 1976. The NationsBank Plaza (now the Bank of America Plaza) opened in 1992. The Underground Atlanta shopping and entertainment complex opened in 1989, and the Georgia Dome in 1992. In 1996, Atlanta hosted the Summer Olympic Games. Construction for the event included a downtown stadium, which afterward—in 1997—became the new home of the Braves. A new park, Centennial Olympic Park, was created downtown.

One of the major problems facing Atlanta's city government continued to be the rebuilding of the aging streets, bridges, and sewerage system. In 1993, a major sewer line collapsed, destroying a parking lot and part of a downtown building.

Recent developments. Voters elected Shirley Franklin mayor in 2001. Franklin, a former city administrator, became the city's first female mayor. Brian P. O'Shea

Atlantic Charter expressed the post-World War II aims of the United States and the United Kingdom of Great Britain and Northern Ireland. President Franklin D. Roosevelt of the United States and Prime Minister Winston Churchill of the United Kingdom adopted the declaration in August 1941 during a conference aboard ship off the coast of the Canadian island of Newfoundland. The complete text is given below.

UPI Bettmann

The Atlantic Charter was adopted at a 1941 meeting between U.S. President Franklin D. Roosevelt, *seated left*, and British Prime Minister Winston Churchill, *seated right*.

Text of the Atlantic Charter

The President of the United States of America and the Prime Minister, Mr. Churchill, representing His Majesty's Government in the United Kingdom, being met together, deem it right to make known certain common principles in the national policies of their respective countries on which they base their hopes for a better future for the world.

First, their countries seek no aggrandizement, territorial or other;

Second, they desire to see no territorial changes that do not accord with the freely expressed wishes of the peoples concerned;

Third, they respect the right of all peoples to choose the form of government under which they will live; and they wish to see sovereign rights and self-government restored to those who have been forcibly deprived of them;

Fourth, they will endeavor, with due respect for their existing obligations, to further the enjoyment by all states, great or small, victor or vanquished, of access, on equal terms, to the trade and to the raw materials of the world which are needed for their economic prosperity;

Fifth, they desire to bring about the fullest collaboration between all nations in the economic field with the object of securing, for all, improved labor standards, economic advancement, and social security;

Sixth, after the final destruction of the Nazi tyranny, they hope to see established a peace which will afford to all nations the means of dwelling in safety within their own boundaries, and which will afford assurance that all the men in all the lands may live out their lives in freedom from fear and want;

Seventh, such a peace should enable all men to traverse the high seas and oceans without hindrance;

Eighth, they believe that all of the nations of the world, for realistic as well as spiritual reasons, must come to the abandonment of the use of force. Since no future peace can be maintained if land, sea, or air armaments continue to be employed by nations which threaten, or may threaten, aggression outside of their frontiers, they believe, pending the establishment of a wider and permanent system of general security, that the disarmament of such nations is essential. They will likewise aid and encourage all other practicable measures which will lighten for peace-loving peoples the crushing burden of armaments.

Atlantic City, New Jersey (pop. 40,517), is one of the largest seaside resorts in the world. It lies on Absecon Island, on the southeast coast of New Jersey (see **New Jersey** [political map]). Roadways connect Absecon Island to the mainland. The Atlantic-Cape May metropolitan area has 354,878 people.

Atlantic City is famous for its gambling casinos and its Boardwalk. The Boardwalk—made of wood, steel, and

Rudi VonBriel

Atlantic City's famous Boardwalk stretches along the Atlantic Ocean for 4 $\frac{1}{2}$ miles (7.2 kilometers). It is lined with restaurants, shops, and hotels with gambling casinos.

concrete—is 60 feet (18 meters) wide. It stretches along the Atlantic Ocean for 4 $\frac{1}{2}$ miles (7.2 kilometers) in Atlantic City. It continues for 2 more miles (3.2 kilometers) in Ventnor City, a community southwest of Atlantic City. The Boardwalk is lined with restaurants, shops, and hotels with gambling casinos.

Also on the Boardwalk is Boardwalk Hall. The renovated 1929 landmark building, formerly called the Convention Center, is a sports stadium and concert hall. It is also the site of the Miss America Pageant each September. Five piers extend into the Atlantic Ocean from the Boardwalk. Places of interest on the piers include an art center and a shopping mall.

Tourism ranks as Atlantic City's chief economic activity. The city has long attracted many vacationers and weekend and holiday visitors. Its first gambling casino opened in 1978. Atlantic City now has about a dozen casinos. The casinos have attracted large numbers of additional visitors to the city. Besides tourism, the city's economic activities include fishing.

Atlantic City has a mayor-council form of government. The city was incorporated in 1854. A Boardwalk was completed in the city in 1870. The present one dates from 1896. In 1976, New Jersey voters approved a referendum to allow gambling casinos in Atlantic City. By law, each casino must be part of a hotel complex with at least 500 guest rooms. The casinos were originally promoted as a way for the city to finance urban renewal. In the late 1900's, after the arrival of the casinos, some areas of the city were rebuilt. But critics point out that there are still other areas in the city in much need of renovation. Critically reviewed by Martin DeAngelis

Atlantic Coastal Plain. See United States (The Coastal Lowlands).

Atlantic Intracoastal Waterway is a sheltered water route used by boats along the Atlantic Coast of the United States. It consists of a series of rivers, estuaries, inland bays, sounds, and inlets, nearly all linked by canals.

United States Army engineers are continually dredging the 1,200-mile (1,930-kilometer) waterway. Its channel has a depth of 12 feet (3.7 meters) or more. Barges and small pleasure boats travel on the waterway. These vessels are exposed to the open ocean for only about 50 miles (80 kilometers) south from Boston, along the Rhode Island coast, and for a 37-mile (60-kilometer) stretch along the New Jersey coast. A canal extends from Philadelphia to Chesapeake Bay. The remainder of the waterway lies back from the shoreline, or is protected by islands and sand bars.

About 175 bridges cross the Atlantic Intracoastal Waterway. Twenty-two lighthouses help guide the vessels. Water locks lift and lower boats to different levels in the Dismal Swamp Canal in eastern Virginia and in eastern North Carolina.

A one-way voyage on the waterway takes about 10 days for small vessels. The trip presents scenery ranging from the busy shipping scenes at New York Harbor to the lonely wilderness along the Carolina coast and the colorful resorts in Florida. Many colonists in America founded settlements on streams and bays of the Atlantic seaboard. They were among the first to use the coastal and inland waterways for travel, trade, and communication along the coast. John Edwin Coffman

See also Canal; Inland waterway.

WORLD BOOK map

The Atlantic Intracoastal Waterway provides a sheltered route for small boats.

Shostal

Atlantic Ocean is the world's second largest ocean. Only the Pacific Ocean is bigger. The Atlantic makes up about 26 percent of the earth's ocean area and 17 percent of its total surface area. The Atlantic Ocean contains many special habitats for marine life. It is a rich source of seafood as well as other valuable resources. The Atlantic has been a major avenue for commerce and an active site for exploration for hundreds of years. The islands and coastal regions of the Atlantic are valuable sites for marine recreation and tourism.

Boundaries and size

The Atlantic Ocean is bordered by North America and South America on the west and by Europe and Africa on the east. The Atlantic connects to the Arctic Ocean south of the Davis Strait, the Greenland Sea, and the Norwegian Sea. It joins the Southern Ocean at 60° south latitude.

The Atlantic Ocean is separated into the North Atlantic and the South Atlantic by the equator. The North Atlantic has a number of seas opening into it. These seas, called marginal seas, include the Caribbean, Labrador, and North seas and the Gulf of Mexico. Some scientists regard the Arctic Ocean as a marginal sea of the North Atlantic. The South Atlantic has no marginal seas.

The widest part of the Atlantic, between Spain and Mexico, extends about 5,500 miles (8,800 kilometers). The narrowest part spans about 1,800 miles (2,900 kilometers), between Brazil and western Africa. The Atlantic is about 9,000 miles (14,500 kilometers) long from north to south, and its area is about 34 million square miles (88 million square kilometers).

The Atlantic seafloor

The continental margin is the part of the Atlantic seafloor that borders the continents. The continental margin consists of (1) the *continental shelf,* (2) the *continental slope,* and (3) the *continental rise.*

The continental shelf slopes gently from the coastline to a depth of approximately 330 feet (100 meters). The width of the continental shelf varies from a few miles or kilometers to about 250 miles (400 kilometers). Beyond the continental shelf, the seafloor drops steeply to about 9,800 feet (3,000 meters). This region is called the continental slope. At the base of this slope is the continental rise, which is a region of sediments that have washed from the continents. From there, the seafloor drops gradually to the *abyssal depths* of about 13,100 feet (4,000 meters).

At some places along the continental shelf, continental slope, and continental rise, erosion has formed submarine canyons and channels. Some of these features occur off rivers. Others may represent ancient patterns of drainage from the continents.

The ocean's large islands lie close to the mainland of the continents and are called continental islands. They include Cuba, Great Britain, Ireland, and Newfoundland in the North Atlantic, and the Falkland Islands in the South Atlantic. The marginal seas have many more islands than the ocean itself.

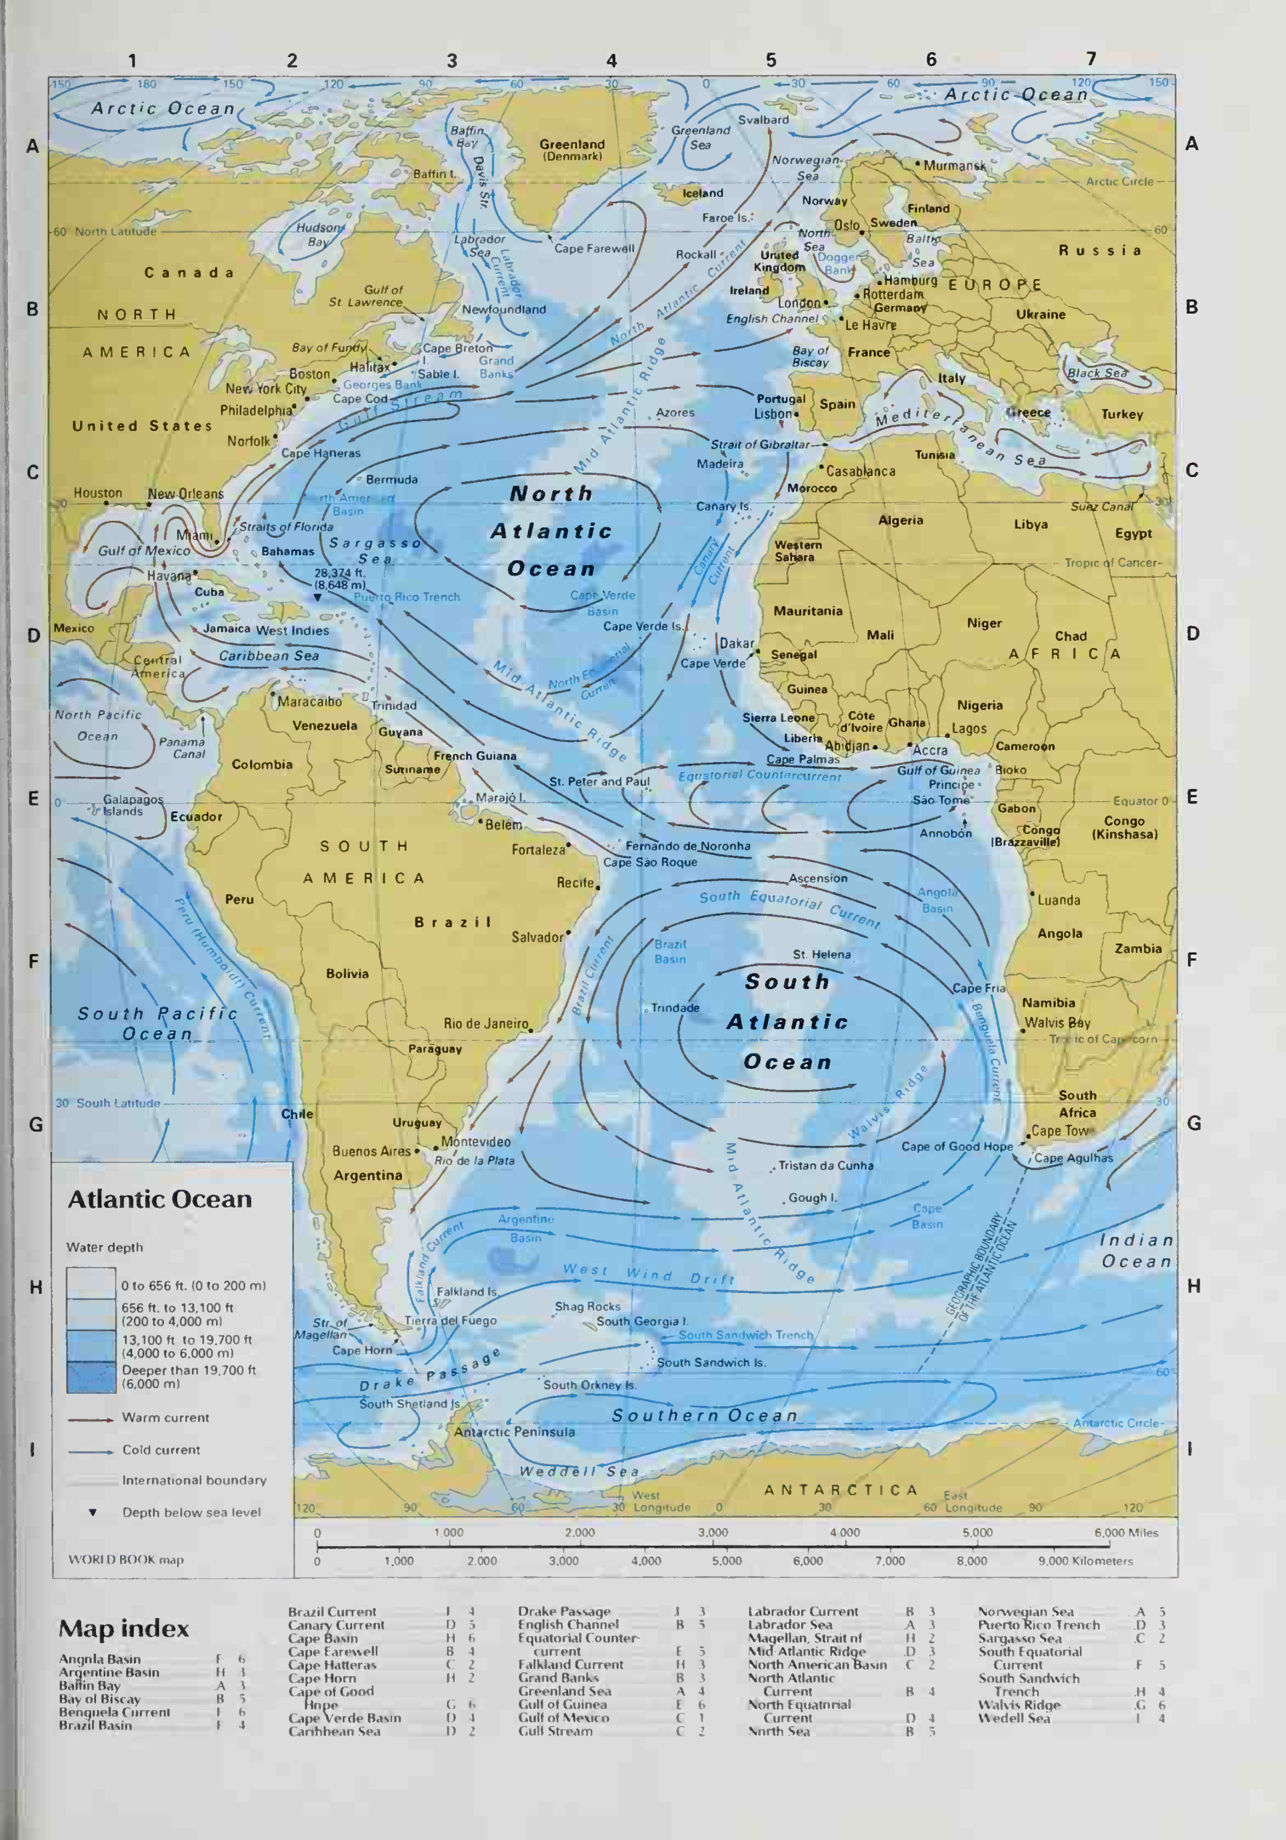
The Mid-Atlantic Ridge is the most striking feature on the floor of the Atlantic Ocean. The Mid-Atlantic Ridge is a submarine mountain range that extends from north of Iceland to the Antarctic Ocean. The ridge forms the boundary between the tectonic plates, rigid slabs of earth's crust that support the continents and make up the seafloor.

New seafloor is created in the rift by *seafloor spreading.* During this process, the tectonic plates move away from the rift. Melted rock rises into the rift and hardens to form the new seafloor. The spreading of seafloor causes the Atlantic to widen about $\frac{1}{2}$ inch (1.3 centimeters) a year.

The Mid-Atlantic Ridge is part of a mid-ocean ridge system that circles the earth. This great mountain range is the site of submarine earthquakes, volcanos, and *hydrothermal vents.* Hydrothermal vents occur when water seeps through cracks in the seafloor and is then heated by underlying volcanic molten rock. The water then rises back to the ocean floor as mineral-rich hot water springs.

The Mid-Atlantic Ridge rises above the ocean surface in several places, forming islands. These islands include Ascension, the Azores, Iceland, and St. Helena. Volcanic islands—that is, those created by the eruption of volcanoes—include Bermuda, the Canary Islands, Cape Verde, Iceland, the Madeira Islands, the South Sandwich Islands, St. Helena, and Tristan da Cunha.

The seafloor slopes gradually away from the Mid-Atlantic Ridge to the *abyssal plains,* which lie mainly at depths of about 14,000 to 18,000 feet (4,300 to 5,500 meters) below sea level. Trenches form the deepest parts of the Atlantic. A small number of trenches occur near the West Indies and off the southern tip of South America. A small number of trenches occur near the West Indies and off the southern tip of South America. The ocean's deepest point is in the Puerto Rico Trench, 28,232 feet (8,605 meters) below the surface.



The ocean depths

The layers of water at the Atlantic's lowest depths are known as *deep waters* and *bottom waters.* They come from the surface and are the only source of oxygen for the life in the deep basin. Deep waters range from about 3,300 to 13,100 feet (1,000 to 4,000 meters) below sea level. Bottom waters range from a depth of about 13,100 feet to the seafloor.

An important water mass, the Antarctic bottom waters, forms along the Antarctic coast, which has the world's coldest ocean waters. When ice forms in the Antarctic, most of the salt separates from the water that freezes and remains in the water that does not freeze. The water that remains liquid becomes extremely dense because of its high salt content and its low temperature. It sinks down the Antarctic slope into the basin. Then, as bottom waters, it moves slowly across the ocean floor into the North Atlantic Ocean, sometimes reaching 45° north latitude.

Climate

The far northern and southern parts of the Atlantic Ocean have long, cold winters and short, cool summers. In these regions, the winter air may be much colder than the water. The variation between surface and air temperature causes low fog, sometimes called *sea smoke,* to form. In the Grand Banks and other areas, warm, moist air moves over cold water, producing

heavy fog that may be dangerous for ships. Icebergs float in the far north and south, and are hazards to navigation. Near the equator, the climate stays hot all year.

Cyclical events also affect weather patterns and climate. For example, El Niño, a warm current in the Pacific Ocean, affects the formation of hurricanes in the Atlantic (see **El Niño**). Another cyclical event, the North Atlantic Oscillation, takes place about every 10 years. It may affect temperature, rainfall, drought, and storm conditions in Europe and Africa.

Water temperatures at the Atlantic's surface range from about 86 °F (30 °C) at and near the equator in summer to about 28 °F (−2 °C) at and near the boundary with the Southern Ocean in winter. In warm and moderate regions, the temperature may vary little from the surface to a depth of about 330 feet (100 meters). In these regions, the temperature drops off quickly below 330 feet. At a depth of about 3,300 feet (1,000 meters), the temperature is about 41 °F (5 °C) and varies little to the ocean floor. In cold regions, temperatures change little between surface and deep waters.

Winds. Wind belts in the Atlantic Ocean include the *trade winds* and the prevailing *westerlies.* The trade winds occur on each side of the equator. The northeast trades blow steadily from Africa to the Caribbean at 5° to 30° north latitude. The southeast trades blow from Africa toward South America at 5° to 30° south latitude. An area of light and variable winds called the *doldrums* occurs between the two trade wind belts.

The westerlies extend from 35° to 60° north latitude and 35° to 60° south latitude. The westerlies in the northern hemisphere influence weather patterns across North America and the Atlantic to Europe. From July through October, tropical storms develop in the area of 10° to 20° north latitude between Africa and Central America. These storms sometimes intensify into powerful hurricanes that can cause great destruction.

Moving ocean waters

Currents along the surface of the Atlantic move in enormous circular patterns called *gyres.* The trade winds and the westerlies drive the gyres, which center in the subtropics. The North Atlantic Gyre is north of the equator, and it circulates clockwise. The South Atlantic Gyre, south of the equator, circulates counterclockwise.

The movement of the trade winds and the westerlies determines the direction of currents in the Atlantic. The trades drive the North and South Equatorial currents from Africa westward. The South Equatorial Current splits at the eastern tip of South America. One portion travels southward, and the other flows to the Caribbean, where it joins the North Equatorial Current. Waters build up in the Gulf of Mexico, resulting in the Gulf Stream, a strong current that sweeps up the North American continent. The current then flows eastward, becoming the North Atlantic Current. This current splits into several routes carrying waters toward the United Kingdom, Iceland, the Norwegian Sea, and Portugal. The southernmost branch continues southward off the coast of Africa as the Canary Current. The South Atlantic Gyre consists of the South Equatorial Current, the Brazil Current, the West Wind Drift, and the Benguela Current.

Other major surface currents in the Atlantic include the Labrador Current, which brings cold water down the east side of North America to about Cape Hatteras; the Equatorial Countercurrent, which flows toward Africa; and the Falkland Current, which brings cold waters into the South Atlantic Gyre circulation.

Tides. Along most of the Atlantic coast, tides reach their maximum height twice each day. The Atlantic's—and the world's—largest difference in high and low tides takes place in Canada's Bay of Fundy, between New Brunswick and Nova Scotia. The daily tidal range in the bay may exceed 50 feet (15 meters). The Gulf of Mexico has only one high and low tide each day. The average range between high and low tides in the gulf is only about 2 feet (0.6 meters). Some places in the gulf have tidal ranges of only a few inches or centimeters. Tides are also small in the Mediterranean.

Ocean life

A wide variety of plant and animal life thrives in the Atlantic Ocean. Plants and plantlike organisms can live only in the sunlit surface waters, to a depth of about 330 feet (100 meters). Animals live throughout the Atlantic.

The surface waters of the continental shelf support one-celled plantlike organisms called *phytoplankton,* which are a major food for marine life. In winter months, surface waters are mixed by strong winds to greater depths. This process increases nutrient concentrations in the upper waters. When spring begins to warm the surface waters, the ocean experiences the year's largest phytoplankton growth, called the *spring bloom.*

The hydrothermal vents on the seafloor support vast communities of marine life. Near these vents, bacteria thrive by using mineral substances from the vents as food. The bacteria, in turn, are consumed by other forms of marine life. Many rare types of shellfish live in hydrothermal vent communities.

In the Sargasso Sea, a type of seaweed called *sargassum weed* grows drifting on the ocean. The weed provides a habitat for small fish, crabs, and other organisms.

Coral communities are found only in warm waters. They are common in the Caribbean and in Bermuda.

Whales migrate over long distances between the warm waters of the tropics and the cooler, plankton-rich waters in coastal and high-latitude areas. In the North Atlantic, whales live in the Caribbean and in the waters around Greenland and the Norwegian Sea. In the South Atlantic, they are found along the coasts of Africa and Brazil and in the waters of the Antarctic Ocean.

Ocean resources

The Atlantic Ocean provides about a fourth of the world's annual catch of fish and shellfish. The leading

Facts in brief

Area: About 34 million mi² (88 million km²).
Greatest distances: *North-south*—9,000 mi (14,500 km). *East-west*—5,500 mi (8,800 km).
Average depth: 12,100 ft (3,700 m).
Greatest depth: 28,232 ft (8,605 m), in the Puerto Rico Trench.
Surface temperatures: *Highest,* about 86 °F (30 °C), near the equator in summer. *Lowest,* 28 °F (−2 °C), at and near the boundary with the Southern Ocean in winter.
Tides: *Highest*—Over 50 ft (15 m), in the Bay of Fundy, Canada. *Lowest*—Less than 1.5 ft (0.5 m) in areas of the Gulf of Mexico and the Mediterranean Sea.

fishing areas include Dogger Bank and the Grand Banks. People raise fish and shellfish on coastal fish farms using a process called *aquaculture*.

Petroleum and natural gas are the Atlantic's most valuable mineral resources. About a fourth of the world's petroleum comes from sediments in the Atlantic's continental shelf. About 70 percent of this petroleum is from marginal seas, especially the Gulf of Mexico and the North Sea. Other valuable mineral products of the Atlantic include gems, sand and gravel, and sulfur.

Pollution

Pollutants enter the ocean from many sources. Rivers and runoff from land bring many wastes to the sea. Many coastal cities discharge treated and untreated wastes into the ocean. Some pollutants are transported through the atmosphere to the ocean. Some wastes enter the ocean from ships. Spills of petroleum and hazardous wastes occur when ships run aground or are damaged by storms. Before the 1980's, factories and power plants commonly discarded industrial and radioactive wastes into the ocean. Ships also incinerated hazardous wastes at sea.

Phytoplankton thrives on certain nutrients produced by the decay of organic matter. Thus, organic pollution can lead to a huge increase in the population of phytoplankton off the continental shelf. The phytoplankton eventually decomposes, consuming more oxygen than normal in the process. The increase in the loss of oxygen can make the waters unfit for marine animals. Under some conditions, the populations of certain phytoplankton species can increase rapidly within a few days. They reach such high concentrations that they affect the color of the water. The water may appear soupy green, brown, or red. These thick growths of phytoplankton, called *blooms,* can kill fish. Some species produce toxins that are absorbed by the fish and shellfish that eat them. Such contaminated seafood can cause poisoning and paralysis in human beings.

Since the 1970's, governments have begun to regulate most uses of the ocean for waste disposal. The regulators strive to use the natural systems and cycles in the ocean to take in wastes in ways that will not harm human beings or the environment. Governments have also taken steps to ban the use of certain pollutants, such as lead, which was once used as an additive in gasoline, and the pesticide DDT. Both substances are widely dispersed in the Atlantic.

Exploration

Early explorers. Phoenician traders began to explore the Atlantic by the 700's B.C. They ventured through the Strait of Gibraltar to trade along the coast of Spain and Morocco. They probably reached the islands of Great Britain and Ireland and the southern part of the continent of Africa by about 600 B.C. Vikings started to explore the North Atlantic in the A.D. 800's. During the next 200 years, they colonized Greenland and Iceland and sailed as far as North America.

During the 1300's and 1400's, exploration of the Atlantic increased rapidly. Many merchants sought new routes from Europe to the Spice Islands of the East Indies. People learned to build better ships, and navigation methods improved. Europeans explored most of the west coast of Africa by the late 1400's. The Portuguese navigator Bartolomeu Dias sailed around the southern tip of Africa in 1488. In 1492, Christopher Columbus made the first of his historic voyages from Europe to North America. His voyages raised great interest in exploration, brought knowledge of the New World to Europe, and proved that ships could safely travel the western Atlantic. During the next 50 years, explorers from such nations as England, France, Portugal, and Spain sailed through most of the Atlantic Ocean.

The beginnings of scientific oceanography. Oceanographers aboard the British research ship *Challenger* made the first major study of the Atlantic floor. In 1873 and 1876, they obtained samples of the Atlantic seabed and of many deep-sea animals and plants.

During the German expedition of the *Meteor* from 1925 to 1927, scientists performed the first extensive survey of the South Atlantic Ocean below the surface. They gathered conclusive evidence for the existence of the Mid-Atlantic Ridge.

New techniques. By the mid-1960's, sonar and other electronic devices enabled geologists to chart much of the Atlantic floor. Beginning in 1968, deep sea drilling of sediments and rocks from the ocean floor provided new information about the ocean basins. Scientists found evidence to support the theory that the Atlantic formed by seafloor spreading over the past 180 million years. They also learned more about the geology and mineral resources of the continental shelf.

During the late 1900's and early 2000's, oceanographic studies of the Atlantic assembled large teams of scientists from many countries. Important scientific studies included the Geochemical Ocean Section Studies (GEOSECS), an international project begun in 1971 to investigate the chemical properties of ocean water. The Joint Global Ocean Flux Study (JGOFS) analyzed the role of carbon in the world's oceans. The World Ocean Circulation Experiment (WOCE) was a 40-nation effort to understand ocean circulation.

The technologies developed for oceanic studies created new opportunities in the area of submarine archaeology. Explorers located many shipwrecks at the bottom of the Atlantic, including the *Titanic,* in the late 1900's. Underwater archaeologists also explored sites from Roman times in the Mediterranean. These sites had remained undisturbed for about 1,000 years, and they offered new opportunities to learn about the past.

Atlantic Provinces are the four Canadian provinces of New Brunswick, Newfoundland and Labrador, Nova Scotia, and Prince Edward Island. Three of the provinces—New Brunswick, Nova Scotia, and Prince Edward Island—are sometimes called the *Maritime Provinces.*

New Brunswick and Nova Scotia form part of the Canadian mainland. Newfoundland and Labrador consists of the island of Newfoundland and the coast of Labrador, a part of the mainland. The Atlantic Provinces cover 208,612 square miles (540,303 square kilometers), or about 5 percent of the total area of Canada.

About 8 percent of Canada's people live in the Atlantic Provinces. The 2001 Canadian census reported that the region had a population of 2,285,729. About two-thirds of the people have some English ancestry. Other large ethnic groups include French, Irish, and Scottish. Indians make up 1 percent of the population. Over half the people live in cities or towns. The three largest communities of the region are, in order of size, Halifax, Nova Scotia; Cape Breton, Nova Scotia; and St. John's, in Newfoundland and Labrador. Simon M. Evans

Atlantic States are states of the United States that lie south of New England and which border on the Atlantic Ocean or are closely tied to it economically. The Middle Atlantic States are New York, New Jersey, and Pennsylvania. The South Atlantic States are Delaware, Maryland, Virginia, North Carolina, South Carolina, Georgia, and Florida. West Virginia is sometimes included in the South Atlantic States.

Atlantis was a legendary continent that many people believe sank into the Atlantic Ocean thousands of years ago. The first mention of Atlantis appeared during the 300's B.C. in *Critias* and *Timaeus,* two works by the Greek philosopher Plato. According to Plato, a brilliant civilization once existed on Atlantis. But its people became corrupt and greedy, and so the gods punished them. During one day and night, great explosions shook Atlantis, and the continent sank into the sea.

Plato's tale of Atlantis fascinated many people of later times. They developed various theories about the location of the continent and how it disappeared. A number of expeditions attempted to discover the remains of Atlantis. Some people have claimed that Atlantis was the basis of all later civilizations. A few have even predicted that the continent will someday rise from the sea.

Today, many scholars believe Atlantis was actually the island of Thira in the Aegean Sea, about 70 miles (110 kilometers) north of the larger island of Crete. Volcanic eruptions destroyed most of Thira about 1470 B.C. and largely wiped out the Minoan civilization, which had thrived on Thira and Crete. Scholars think these events inspired Plato's description of Atlantis. C. Scott Littleton

Atlas is a collection of maps usually displayed in a printed book or viewed on a computer. Most printed atlases also contain charts and tables. Many have photographs, including images taken by cameras on satellites. Most atlases show places on Earth, but there are also atlases of the moon, other planets, and the stars.

Typical maps in atlases show countries, cities, and towns as well as land features, such as rivers and mountains. Some maps show the distribution of a particular feature, such as population or rainfall, over an area. An index lists the place names shown on the maps. The index also tells where to find the places on the maps.

WORLD BOOK photo by Steinkamp/Ballogg

An atlas aids the study of geography. Many atlases have large pages so the maps can show areas in detail.

Many atlases contain text related to information given in maps, charts, tables, and photographs. An atlas that covers a small area, such as a state, or a special subject, such as agriculture, often has a relatively large amount of text. A general atlas of the world has little text.

Electronic atlases provide rapid access to maps. The user of an electronic atlas can type in a place name, and a map will show the location of the place. Some electronic atlases have audio clips that describe the location.

Electronic road atlases that are built into automobiles display maps on a small computer screen. A driver can set some of these atlases to make the map on the screen always show the location of the car.

History. In the A.D. 100's, Ptolemy, an astronomer and geographer who lived in Egypt, published what some historians consider the first atlas. This work contained a variety of maps as well as information on *cartography,* the study and making of maps.

In the late 1500's, the Dutch cartographer Abraham Ortelius and the Flemish cartographer Gerardus Mercator developed more accurate atlases. These books contained maps of vast regions that were unknown to Ptolemy. Ortelius's work, published in 1570, is considered the first modern atlas. Mercator's work, which followed, was the first to use the title *Atlas* for a collection of maps. At the front of the book was an illustration of the Greek god Atlas supporting Earth on his shoulders.

Before printing was invented, cartographers drew all the maps in each atlas by hand. The invention of printing boosted atlas production. But cartographers still had to make by hand the woodcuts and metal engravings for the maps. Later, cartographers hand-drew maps that were photographically transferred to printing plates. Today, they use computers to create maps. Judy M. Olson

Atlas, in Greek mythology, was one of a group of gods called Titans. He was the son of the Titan Iapetus and a

Marble statue by an unknown Roman sculptor; Museo Archeologico Nazionale, Naples, Italy (EPA Alinari)

Atlas was forced by Zeus, king of the gods, to support the sky forever. In this sculpture, the sphere represents the sky.

sea nymph named Clymene, and the brother of Prometheus. Atlas and the other Titans fought an unsuccessful war against Zeus and the other Olympian gods. Zeus punished Atlas by forcing him to stand and support the sky on his shoulders forever.

The famous Greek hero Hercules asked Atlas for help in taking the apples of the Hesperides (see **Hesperides**). Atlas went to get the apples, leaving Hercules to hold up the sky. When he returned with the apples, Atlas refused to take back the sky, hoping to force Hercules to support it permanently. But Hercules outwitted Atlas and deceived him into taking up the sky again.

Atlas stood in the northwest region of what is now Africa. The Atlas Mountains, which are located in northwestern Africa, were named for him. Books of maps also are named for Atlas. Many works of art show Atlas supporting the earth, rather than the sky, on his shoulders.

William F. Hansen

Atlas Mountains extend for 1,500 miles (2,410 kilometers) across northwestern Africa. They run from Cape Rhir on the Atlantic Ocean to Cape Bon on the Mediterranean Sea, and cross part of Morocco, Algeria, and Tunisia (see **Africa** [terrain map]). They were named for Atlas, the Greek Titan (see **Atlas**).

The Atlas Mountains are made up of several chains that run from southwest to northeast. The southern chains are the Grand, or High, Atlas and Anti-Atlas in Morocco and the Saharan Atlas in Algeria. The southern and northern chains are separated by high plateaus. These northern Atlas chains rise along the Mediterranean coast: the Rif Atlas in Morocco; the Tell Atlas in Algeria; and the Tunisian Atlas. The highest peaks in the Atlas Mountains include Jebel Toubkal (13,665 ft., or 4,165 m) and Irhil M'Goun (13,356 ft., or 4,071 m) in Morocco's Grand Atlas.

Phosphate rock, iron ore, and manganese are mined in the Atlas Mountains. Plant life of the northern regions resembles that of Mediterranean Europe. *Esparto* (alfa grass) grows on the high plateaus. It is used to make fiber, paper, and rope. Only scrubby vegetation grows on the southern slopes. Hartmut S. Walter

Atmosphere is a measure of atmospheric pressure. One atmosphere is a pressure 14.696 pounds per square inch of surface. One atmosphere equals 101.325 kilopascals in the metric system. See also **Barometer; Boiling point; Pressure.**

Atmosphere is the mass of gases that surrounds a planet or other heavenly body. Scientists divide Earth's atmosphere into five layers: the *troposphere,* the *stratosphere,* the *mesosphere,* the *thermosphere,* and the *exosphere.* For information on the atmospheres of other planets, see the separate articles such as **Venus.** See also **Air; Earth** (The atmosphere; Earth's early development); **Mesosphere; Planet** (The planets of our solar system); **Stratosphere; Thermosphere; Troposphere.**

Atoll, *AT ahl,* is a circular ring of coral in the open sea, built up on a sunken bank, or formed on the crater of a

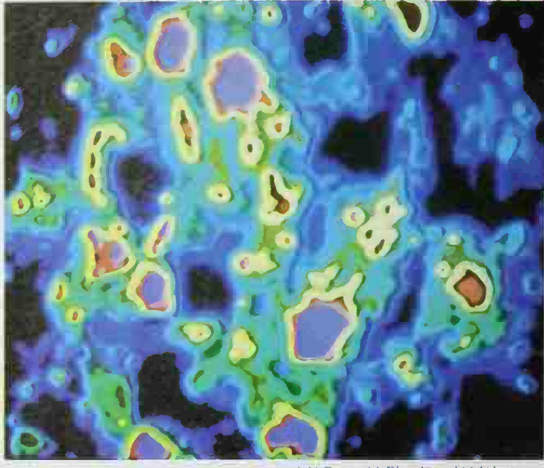
© Karen Lukas, Photo Researchers

An atoll, such as the one shown in this photograph, is a circular island that surrounds a body of water called a *lagoon.* The cross-section drawing shows that the ring-shaped coral reef making up an atoll completely encloses the lagoon, *dark area.*

volcano that has sunk below the surface of the sea. A thin layer of soil generally lodges on the reef, and vegetation springs up. Tropical plants thrive on the atoll, and it becomes a coral island. Atolls enclose shallow pools or lagoons. One or more channels usually connect the lagoon of most atolls to the surrounding sea, on the windward side. Atolls are found chiefly in the Pacific Ocean. See also **Coral**. Peter P. Sakalowsky, Jr.

Atom is one of the basic units of matter. Everything around us is made up of atoms. An atom is incredibly tiny—more than a million times smaller than the thickness of a human hair. The smallest speck that can be seen under an ordinary microscope contains more than 10 billion atoms. The diameter of an atom ranges from about 0.1 to 0.5 nanometer. A nanometer is a billionth of a meter, or $\frac{1}{25,400,000}$ inch.

Atoms form the building blocks of the simplest substances, the *chemical elements*. Familiar elements include hydrogen, oxygen, iron, and lead. Each element consists of one basic kind of atom. *Compounds* are more complex substances made of two or more kinds of atoms linked in units called *molecules*. Water, for example, is a compound in which each molecule consists of two atoms of hydrogen linked to one atom of oxygen.

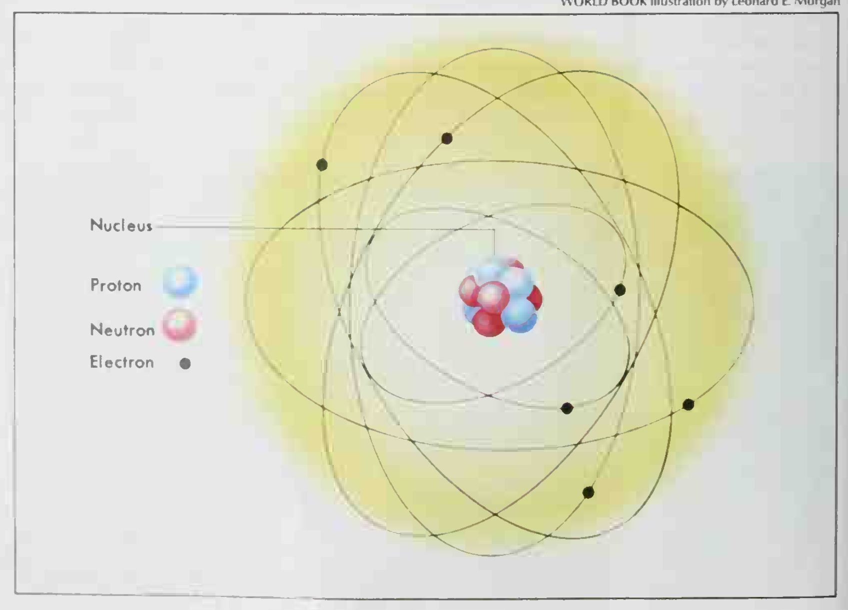


Atoms vary greatly in weight, but they are all about the same size. For example, an atom of plutonium, the heaviest element found in nature, weighs more than 200 times as much as an atom of hydrogen, the lightest known element. However, the diameter of a plutonium atom is only about 3 times that of a hydrogen atom.

The parts of an atom

Tiny as atoms are, they consist of even more minute particles. The three basic types are *protons, neutrons,* and *electrons*. Each atom has a definite number of these *subatomic* particles. The protons and neutrons are crowded into the *nucleus*, an exceedingly tiny region at the center of the atom. If a hydrogen atom were about 4 miles (6.4 kilometers) in diameter, its nucleus would be no bigger than a tennis ball. The rest of an atom outside the nucleus is mostly empty space. The electrons whirl through this space, completing billions of trips around the nucleus each millionth of a second. The fantastic speed of the electrons makes atoms behave as if they were solid, much as the fast-moving blades of a fan prevent a pencil from being pushed through them.

Atoms are often compared to the solar system, with



Robert H. March, the contributor of this article, is Emeritus Professor of Physics at the University of Wisconsin-Madison and the author of Physics for Poets.

A. V. Crewe, M. Ohtsuki, and M. Utlaut, Enrico Fermi Institute, University of Chicago

Individual atoms of the metals platinum and palladium magnified about 3 million times appear as yellow dots in this photo made with an electron microscope. The yellow areas with red or purple centers are clusters of atoms. Color was added electronically to improve the image. Atoms themselves have no color.

WORLD BOOK illustration by Leonard E. Morgan

The parts of an atom

An atom consists of three basic types of particles called *protons, neutrons,* and *electrons*. Protons have a positive electric charge, and electrons have a negative charge. Neutrons are electrically neutral. The protons and neutrons are clustered in the *nucleus*, a tiny region near the center of the atom. The electrons whirl at fantastic speeds through the empty space outside the atom's nucleus.

the nucleus corresponding to the sun and the electrons corresponding to the planets that orbit the sun. This comparison is not completely accurate, however. Unlike the planets, the electrons do not follow regular, orderly paths. In addition, the protons and neutrons constantly move about at random inside the nucleus.

The nucleus makes up nearly all the *mass* of an atom. Mass is the quantity of matter in an atom. Each proton has a mass roughly equal to that of 1,836 electrons. It would take 1,839 electrons to equal a neutron's mass. Each proton carries one unit of positive electric charge. Each electron carries one unit of negative charge. Neutrons have no charge. Under most conditions, an atom has the same number of protons and electrons, and so the atom is electrically neutral.

Protons and neutrons are about 100,000 times smaller than atoms, but they are in turn made up of even smaller particles called *quarks*. Each proton and neutron consists of three quarks. In the laboratory, scientists can cause quarks to combine and form other kinds of subatomic particles besides protons and neutrons. All these other particles break down and change into ordinary particles in a small fraction of a second. Thus, none of them is found in ordinary atoms. However, scientists first learned that protons and neutrons consist of quarks through the study of other subatomic particles. For information on these other particles, see **Subatomic particle** and the separate articles on subatomic particles listed in the *Related articles* at the end of this article.

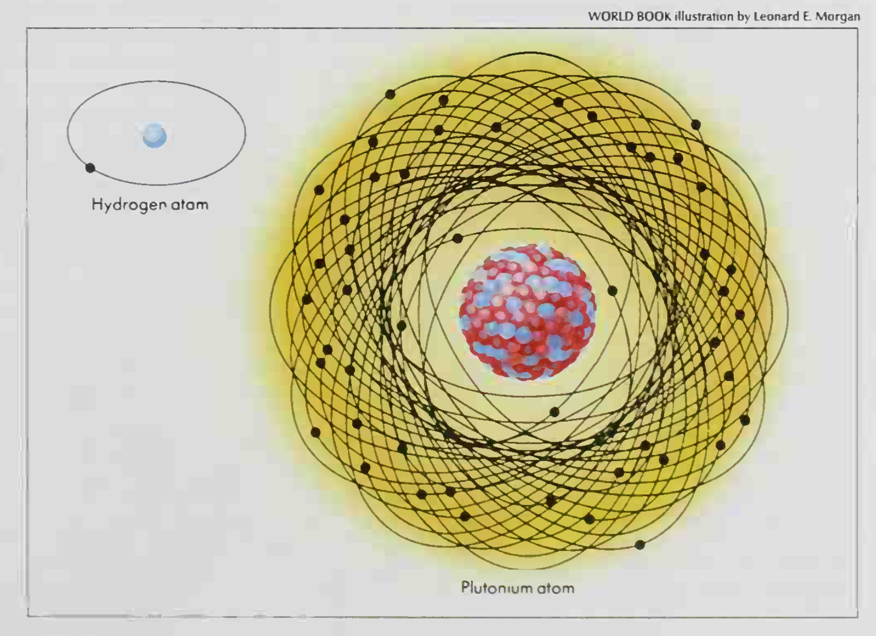
The electrons, unlike the protons and neutrons, do not seem to have smaller parts. Electrons have very little mass. The mass of an electron in grams may be written with a decimal point followed by 27 zeros and a 9.

Opposite electric charges attract. The positively charged nucleus therefore exerts a force on the negatively charged electrons that keeps them within the atom. However, each electron has energy and so is able to resist the attraction of the nucleus. The more energy an electron has, the farther from the nucleus it will be.

Thus, electrons are arranged in *shells* at various distances from the nucleus according to how much energy they have. Electrons with the least energy are in inner shells, and those with more energy are in outer shells.

Each electron shell is labeled with a number. The shell closest to the nucleus is called shell 1. The other shells, in order of increasing distance from the nucleus, are shells 2, 3, 4, 5, 6, and 7. The shells are sometimes named by the letters K, L, M, N, O, P, and Q. Each shell can hold only a limited number of electrons. Shell 1 can hold no more than 2 electrons. Shell 2 can hold 8 electrons, shell 3 can hold 18, and shell 4 can hold 32. In theory, shell 5 can hold 50 electrons, shell 6 can hold 72, and shell 7 can hold 98. However, these outer shells are never completely filled.

The properties of atoms



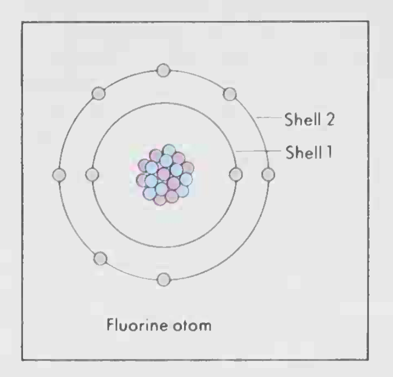
The atomic number tells how many protons an atom has. All atoms of the same element have the same number of protons. For example, every hydrogen atom has a single proton, and so the atomic number of hydrogen is 1. The atomic numbers for other natural elements range successively up to 92 for uranium, which has 92 protons in each atom. Tiny amounts of plutonium, which has an atomic number of 94, also occur naturally. Elements whose atoms have more than 92 protons can be created in the laboratory.

The atomic number determines an element's place in the *periodic table*. This table organizes the elements into groups with similar chemical properties. For a reproduction of the table, see **Element, Chemical**.

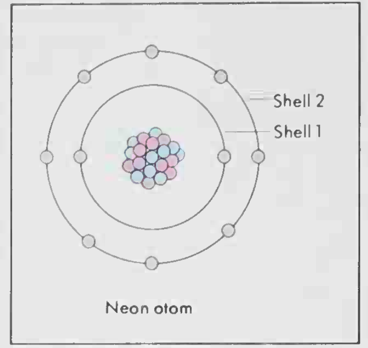
The mass number is the sum of the protons and neutrons in an atom. Although all atoms of an element have the same number of protons, they may have different numbers of neutrons. Atoms that have the same number of protons but different numbers of neutrons are called *isotopes*.

Most of the elements in nature have more than one isotope. Hydrogen, for example, has three. In the most

WORLD BOOK illustration by Leonard E. Morgan

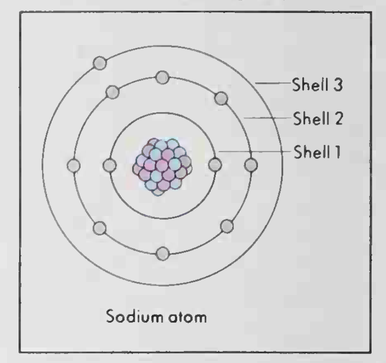


How atoms compare in weight and size



Atoms vary greatly in weight, but they are all about the same size. The smallest and lightest atom is the hydrogen atom. It consists of 1 proton and 1 electron. The largest and heaviest atom found in nature is the plutonium atom. It has 94 protons, 150 neutrons, and 94 electrons. An atom of plutonium weighs more than 200 times as much as an atom of hydrogen. However, a plutonium atom is only about 3 times as large in diameter as a hydrogen atom.

Electron shells and chemical behavior An atom's electrons are arranged in *shells*. Starting with the innermost, the shells are numbered 1 through 7. Each shell can hold only a certain number of electrons. For example, shell 2 can hold eight. In chemical reactions, the outermost shell gains, loses, or shares electrons.



WORLD BOOK diagrams by Zorica Dabich

A fluorine atom has seven electrons in shell 2. The atom fills the shell by accepting one electron from another atom.

In a neon atom, shell 2 is filled. As a result, neon generally does not enter into chemical reactions with other atoms.

A sodium atom tends to lose its single electron in shell 3. The filled shell 2 then becomes the outermost shell.

common hydrogen isotope, the nucleus consists only of a proton. In the two other hydrogen isotopes, the nucleus consists of one or two neutrons in addition to the proton. Scientists use the mass number to distinguish the three isotopes as hydrogen 1, hydrogen 2, and hydrogen 3. They also refer to hydrogen 1 as *protium,* to hydrogen 2 as *deuterium,* and to hydrogen 3 as *tritium.*

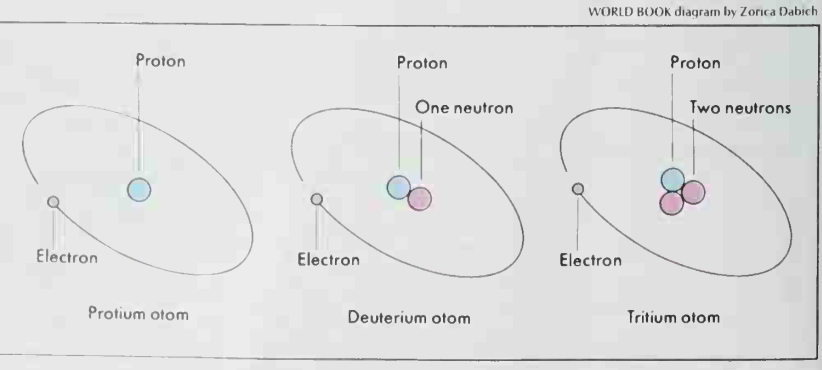
In most lighter elements, the nucleus of each atom contains about an equal number of protons and neutrons. Most heavier elements, however, have more neutrons than protons. The heaviest elements have about 3 neutrons for every 2 protons. For example, uranium 238 has 146 neutrons and 92 protons.

Atoms that have the same mass number but different atomic numbers are called *isobars.* Thus, isobars are atoms of different elements. For example, the isobars argon and calcium have a mass number of 40, but argon's atomic number is 18 and calcium's is 20.

Atomic weight is the weight of an atom expressed in *atomic mass units* (amu). One amu, also called a *dalton,* equals $\frac{1}{12}$ the weight of an atom of carbon 12. For most atoms, the weight in amu is extremely close to the mass number. Atomic mass units are very small. There are 602 billion trillion amu in a gram.

Scientists determine the atomic weight of an element with more than one isotope by averaging the weights of all the isotopes in the proportions in which they occur in nature. For example, the atomic weight of chlorine is 35.453 amu. This value is an average for the two isotopes chlorine 35 (atomic weight 34.96885) and chlorine 37 (atomic weight 36.96590) in their natural proportions.

Electric charge. Although an atom is normally electrically neutral, it can lose or gain a few electrons in some chemical reactions or in a collision with an electron or another atom. This gain or loss of electrons produces an electrically charged atom called an *ion.* An atom that loses electrons becomes a *positive ion,* and an atom that gains electrons becomes a *negative ion.* The gain or loss of electrons is called *ionization.*



Chemical behavior. The chemical behavior of an atom is determined largely by the number of electrons in its outermost shell. When atoms combine and form molecules, electrons in the outermost shell are either transferred from one atom to another or shared between atoms. The number of electrons involved in this process is called the *valence.* The atoms of some elements can have more than one valence, depending on the number and kind of atoms with which they combine.

If an atom tends to lose electrons to other atoms, its valence is positive. If an atom tends to gain electrons, its valence is negative. For example, sodium tends to lose its one electron and thus has a valence of +1. Chlorine tends to accept one electron from another atom and so has a valence of −1. A molecule of ordinary table salt

WORLD BOOK diagram by Zorica Dabich

The isotopes of hydrogen

Isotopes are atoms of the same element that have different numbers of neutrons. Hydrogen, for example, has three isotopes. In *protium,* the most common hydrogen isotope, the nucleus consists of one proton. The nucleus of an atom of *deuterium* has one proton and one neutron. Two neutrons and a proton make up the nucleus of the third hydrogen isotope, *tritium.*

consists of one atom of sodium linked to one atom of chlorine. The sodium atom donates the electron that chlorine is able to accept.

Radioactivity. In some atoms, the nucleus can change naturally. Such an atom is called *radioactive.* The change in the nucleus may be only in the arrangement of the protons and neutrons. Or the actual number of protons and neutrons may change. When a nucleus changes, it gives off radiation. This radiation consists of alpha or beta particles or gamma rays. Atoms of uranium, radium, and all other elements heavier than bismuth are radioactive. Some isotopes of lighter elements are also radioactive. In addition, physicists can create radioactive isotopes of nearly all elements in a laboratory by bombarding atoms with subatomic particles.

The type of radiation given off by a radioactive nucleus depends on the way the nucleus changes. Gamma rays are given off if only the arrangement of the protons and neutrons in the nucleus changes. But alpha or beta radiation is given off if the number of protons and neutrons in the nucleus changes. The atom then becomes an atom of a different element. This process is called *transmutation.* See Transmutation of elements.

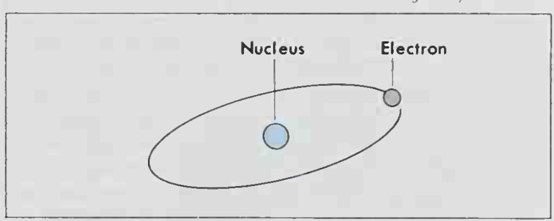
The forces within an atom

The field of physics called *quantum mechanics* deals with the forces inside an atom and the motions of subatomic particles. This field began in 1913, when the Danish physicist Niels Bohr used the *quantum theory* to explain the motion of electrons in atoms. See Quantum mechanics.

Electron energy levels. According to quantum mechanics, electrons cannot have just any amount of energy. Instead, electrons are restricted to a limited set of motions, each of which has a specific value of energy. These motions are called *quantum states* or *energy levels.* When an electron is in a given quantum state, it does not absorb or give off energy. For this reason, an atom can gain or lose energy only if one or more electrons change their quantum state.

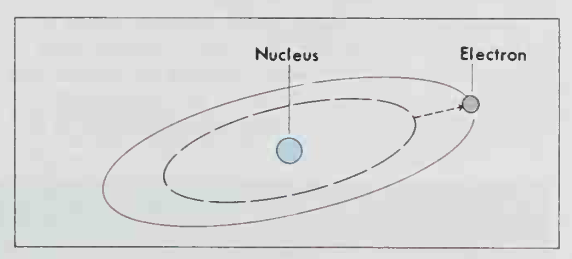
Just as water always seeks its lowest possible level, electrons seek the state of lowest energy. However, only one electron at a time can occupy each quantum state. If the lower states are filled, other electrons are forced to occupy higher states. If all electrons are in the lowest possible state, the atom is in its *ground state.* This condition is normal for atoms at ordinary temperatures.

When matter is heated to temperatures higher than a few hundred degrees, energy is available to raise one or more electrons to a higher energy level. The atom is then in an *excited state.* However, atoms rarely remain in an excited state for more than a fraction of a second. An excited electron almost immediately drops to a lower state and continues dropping until the atom returns to its ground state. At each succeeding drop, the electron gives off a tiny packet of radiant energy called a *photon.* The energy of the photon equals the difference between the two energy levels of the electron. The photons given off by electrons are detected as visible light and other forms of electromagnetic radiation.



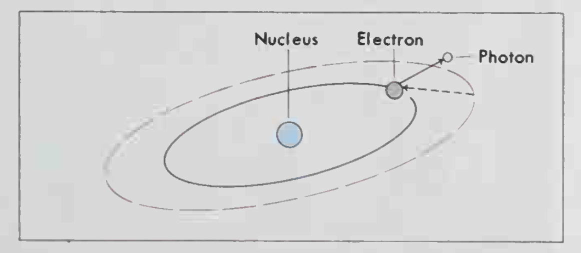
Bohr originally described the quantum states of electrons as orbits like those of the planets around the sun. However, physicists now know that this description is incorrect because an electron is not simply a particle. An electron also has some characteristics of a wave. It is difficult to imagine how something could be both a particle and a wave. This difficulty is one of the problems scientists have in trying to describe the atom to nonscientists. To do so, scientists must use familiar ideas based on our knowledge of the world as we observe it. But conditions inside the tiny atom differ greatly from those in our everyday world. For this reason, physicists can describe the motions of electrons accurately and completely only in mathematical terms.

Forces in the nucleus. The quantum rules that govern the motions of electrons also apply to the motions of protons and neutrons clustered inside the nucleus. However, the force that keeps the nuclear particles together differs greatly from the electrical attraction that holds the electrons within the atom. Each nuclear particle is attracted to its nearest neighbor by what is called the *strong nuclear force* or *strong interaction.* Like electric charges repel each other. However, the power-



Electron energy levels in an atom

An electron in an atom cannot have just any amount of energy. Instead, it is restricted to a limited set of motions, each with a specific value of energy. These motions are called *energy levels* or *quantum states.* An electron absorbs or gives off energy only when it changes from one energy level to another.



WORLD BOOK diagrams by Zorica Dabich

In this atom, the electron is in its lowest possible energy level. Physicists say that such an atom is in its *ground state.*

Heating the atom provides energy to raise the electron to a higher energy level. The atom is now in an *excited state.*

The electron drops back almost immediately. As it does so, it gives off energy in the form of a *photon* (particle of light).

ful nuclear force overcomes the mutual repulsion of the positively charged protons. It thus keeps the nucleus from flying apart. This force dies off quickly, however, unless the nuclear particles are extremely close together. Electrons are immune to the nuclear force.

The nuclear force is highly complicated, and no exact mathematical description of it has been formulated. Nevertheless, a theory known as the *nuclear shell model* provides reasonably accurate estimates of the energy levels in the nucleus.

One neutron and one proton can occupy each quantum state in the nucleus. For this reason, a light nucleus has a nearly equal number of protons and neutrons. But a proton and a neutron in the same state do not have the same amount of energy. Each proton is electrically repelled by all other protons in the nucleus, which increases its energy. In a nucleus with many protons, the difference in energy levels between protons and neutrons is considerable, and more low-energy states are available for neutrons than for protons. This is why a heavy nucleus has more neutrons than protons.

How scientists study atoms

Scientists use a variety of instruments and techniques to study atoms. The devices and methods used depend on whether the researchers are studying atoms themselves, electrons, nuclear particles, or quarks.

Researchers use X rays to study the arrangements of atoms in regular, repeated patterns, such as in crystals. When X rays pass through a crystal, the atoms in the crystal *diffract* (spread out) the X rays in a certain way. These diffracted rays produce patterns on photographic film that reveal how far apart the atoms are and how they are arranged. Extremely powerful *scanning electron microscopes, scanning tunneling microscopes,* and *field-emission microscopes* enable scientists to observe the positions of individual atoms. However, these instruments cannot reveal any details of the structure of atoms.

Scientists study the energies of electrons chiefly by analyzing the light given off by atoms in heated gases. Instruments called *spectrometers* break up the light into a spectrum with a separate line for each wavelength of light. Each wavelength is related to the difference in energy between two quantum states in the atom. After determining the wavelengths, scientists can draw up a complete list of energy levels. With the aid of quantum mechanics, they can then obtain a description of the electron motions in the atom.

Most of what scientists know about nuclear structure has come from experiments with *particle accelerators.* These devices bombard the nucleus with beams of high-energy electrons or protons. The swift-moving electrons or protons can disrupt the motion of particles in the nucleus and occasionally even knock some of them loose. In some experiments, whole nuclei are accelerated and smashed into stationary nuclei. Nuclear physicists have developed a wide variety of detectors for observing the particles that emerge from these collisions. Most of the detectors produce an electric signal when a particle passes through them.

Particle accelerators are also used to study the behavior of quarks. But such studies require particles with much greater energies than those used to study atomic nuclei. Thus, much more powerful accelerators are required.

Development of the atomic theory

The idea that everything is made up of a few simple parts originated during the 400's B.C. in the philosophy of *atomism.* Atomism was founded by the Greek philosopher Leucippus, but his disciple Democritus developed the philosophy more fully. Democritus gave his basic particle the name *atom,* which means *uncuttable.* He imagined atoms as small, hard particles, all composed of the same substance but of different sizes and shapes. During the 300's B.C., a Greek philosopher named Epicurus incorporated Democritus's ideas about atoms into his philosophy. About 50 B.C., the Roman philosopher and poet Lucretius presented the fundamental principles of atomism in his long poem, *On the Nature of Things.* See **Atomism**.

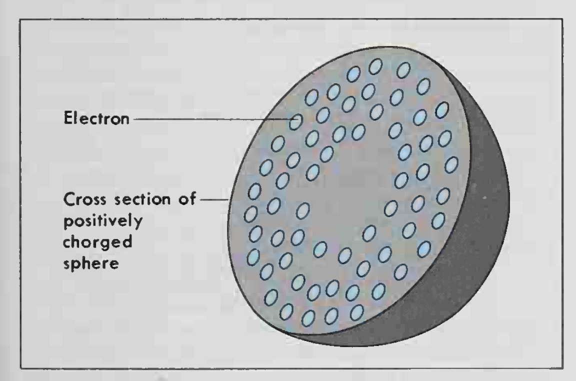
During the Middle Ages, the idea of atoms was largely ignored. This neglect resulted partly from the fact that atomism had been rejected by Aristotle, an ancient Greek philosopher whose theories dominated medieval philosophy and science. The idea that atoms form the basic units of all matter did survive, however. During

Fermilab Visual Media Services

Tracks of particles that make up atoms and other bits of matter are displayed on computers at a research laboratory, *left.* At this lab, a machine called a *particle accelerator* collides particles at almost the speed of light. The collisions produce other particles whose tracks are recorded by computerized detectors. Researchers use computer displays and printouts to study the particles.

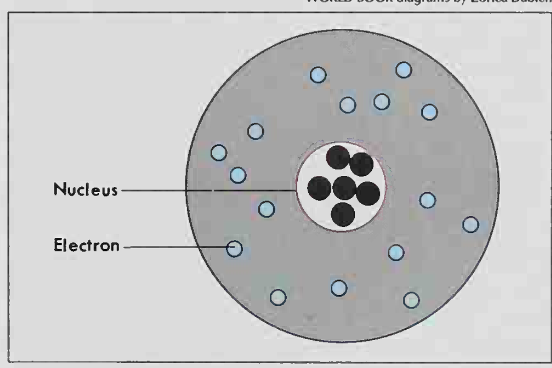
the 1500's and 1600's, such founders of modern science as Francis Bacon and Isaac Newton of England and Galileo of Italy believed in atoms. But those scientists could add little more to the atomic theory than Democritus had described.

The birth of the modern atomic theory. In 1750, Rudjer Boscovich, a scientist born in what is now Croatia, suggested that Democritus might have been wrong in believing that atoms are "uncuttable." Boscovich thought that atoms contain smaller parts, which in turn contain still smaller parts, and so forth down to the fundamental building blocks of matter. He felt that these building blocks must be geometric points with no size at all. Today, most atomic physicists accept a modern form of this idea.



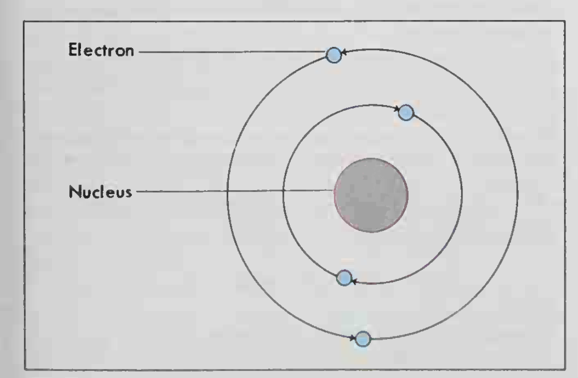
The development of the atomic theory advanced greatly when chemistry became an exact science during the late 1700's. Chemists discovered that they could combine elements to form compounds only in certain fixed proportions according to mass. In 1803, a British chemist named John Dalton developed an atomic theory to explain this discovery. Dalton proposed that each element consists of a particular kind of atom and that the varying properties of the elements result from differences in their atoms. He further suggested that all atoms of a given element are identical in size, shape, and mass. According to Dalton's theory, when atoms combine and form a particular compound, they always combine in a specific numerical ratio. As a result, the composition by mass of a particular compound is always the same.

The first descriptions of atomic structure. In 1897, a British physicist named Joseph John Thomson discovered that atoms are "cuttable." He made this discovery while studying the rays that travel between charged metal plates in a vacuum tube. Thomson determined that the rays consisted of lightweight, negatively charged particles. He had thus discovered electrons. Thomson immediately realized that the electrons must be part of the atom. He proposed a model of the atom in which negatively charged electrons were embedded in a positively charged sphere. Although Thomson's description was far from correct, his work encouraged other scientists to investigate the structure of the atom.

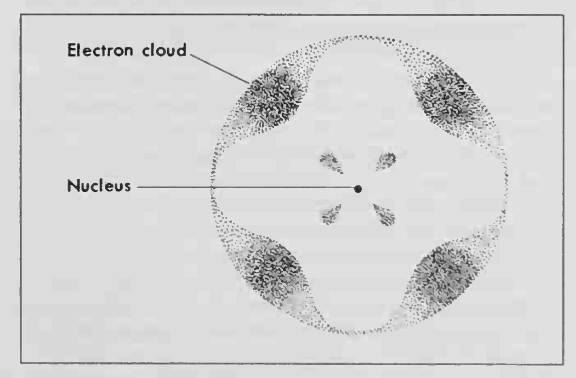


In 1911, the British physicist Ernest Rutherford presented his theory of atomic structure. Rutherford, a former student of Thomson's, declared that nearly all the mass of an atom is concentrated in a tiny nucleus. He also stated that the nucleus is surrounded by electrons

Models of the atom During the 1900's, physicists proposed various models of atomic structure. These diagrams show the three most important early models and a present-day model.



WORLD BOOK diagrams by Zorica Dabich



The Thomson model was proposed by the British physicist Joseph John Thomson in 1904. It showed the electrons embedded in a positively charged sphere like seeds in a watermelon.

The Rutherford model showed the atom's mass concentrated in a positively charged nucleus surrounded by electrons. Ernest Rutherford, a British physicist, proposed this model in 1911.

The Bohr model, proposed in 1913 by the Danish physicist Niels Bohr, described the electron structure. It showed the electrons traveling in fixed orbits around the nucleus.

The electron cloud model, a currently accepted model, indicates the regions within the atom where electrons may be found. Electrons are most likely to be where a cloud is darkest.

traveling at tremendous speeds through the atom's outer regions.

Rutherford based his theory on the results of experiments in which he bombarded thin sheets of gold with alpha particles. Most of the particles passed through the sheets, which showed that the gold atoms must consist chiefly of empty space. But some particles bounced back as if they had hit something solid. Rutherford concluded that these particles had been reflected by a strong force from the tiny but heavy nucleus of an atom.

Rutherford's theory did not explain the arrangement of electrons in atoms. In 1913, however, a description of the electron structure was proposed by Niels Bohr, a Danish physicist who had worked with Rutherford. Bohr suggested that electrons could travel only in a certain set of orbits around the nucleus. Bohr's original, crude picture of the atom was inadequate, but many of the ideas behind it proved correct. In 1924, the French physicist Louis de Broglie proposed that electrons have some properties of waves. By 1928, a correct description of the arrangement of electrons had been obtained with the help of other physicists, especially Erwin Schrödinger and Wolfgang Pauli of Austria and Max Born and Werner Heisenberg of Germany.

Studying the nucleus. Although physicists understood the motions of electrons by 1928, the nucleus remained largely a mystery. Protons had been identified in 1902, and Rutherford had proposed in 1914 that they must form part of the nucleus. In 1932, a British physicist named James Chadwick discovered the nucleus also contains uncharged particles, or neutrons. Also in the early 1930's, scientists developed particle accelerators capable of producing energies high enough to study the nucleus.

The pioneers of nuclear physics did not expect that they would soon see a practical use for their knowledge. In 1938, however, researchers discovered that bombarding the nucleus of a uranium atom with a neutron caused the nucleus to split into two parts and release energy. They called the process *nuclear fission.* The discovery came a few months before the start of World War II in 1939, and fission was used in atomic bombs that helped end the war in 1945.

The development of atomic weapons made governments aware of the importance of nuclear physics. As a result, they provided great sums of money for nuclear research after the war. The funds made possible the construction of accelerators of increasing size and energy. As these accelerators revealed more and more details of the nucleus, researchers realized that the proton and neutron could not be simple objects. They also found that the neutron did not completely lack an electric charge. Instead, it contained equal amounts of positive and negative charge. In addition, researchers discovered hundreds of new particles. These particles were sufficiently similar to one another and to protons and neutrons to suggest that all nuclear particles might be merely different arrangements of a few simple parts.

Recent discoveries. By 1964, researchers had turned up enough clues to indicate what the fundamental parts of protons, neutrons, and other nuclear particles might be like. Two California Institute of Technology physicists, the American Murray Gell-Mann and Russian-born George Zweig, thus proposed a theory describing these parts. Gell-Mann named the parts *quarks.* According to this theory, quarks are always combined in groups of two or three. The original theory required only three kinds of quarks, *up* (or *u*), *down* (or *d*), and *strange* (or *s*), to make up protons, neutrons, and the other particles. But by 1977, experimenters had found not only the u, d, and s, but also a *charm* (or *c*) and a *bottom* (or *b*) quark.

Physicists concluded that a sixth quark, which they named the *top* (or *t*), must also exist. In 1995, scientists at Fermi National Accelerator Laboratory near Batavia, Illinois, announced that they had found the top quark. Physicists are almost certain that there are no more quarks to discover. Robert H. March

Atomic bomb. See Nuclear weapon.

Atomic clock is a device for measuring time intervals by measuring the frequency of electromagnetic waves given off or absorbed by atoms or molecules. In an atomic clock, such frequencies are extraordinarily stable, so the clock is very accurate. Some clocks would gain or lose no more than a second in 1 million years. Atoms and molecules used in atomic clocks include cesium atoms, hydrogen atoms, and molecules of ammonia gas. Atomic clocks control the time signals sent out to the world from national laboratories, such as the National Institute of Standards and Technology. In 1958, scientists throughout the world adopted the vibration rate of an atomic clock as the standard for defining time units. James Jespersen

Atomic energy. See Nuclear energy.

Atomic Energy Commission (AEC) was a United States government agency that directed the development and use of atomic energy. Created by Congress in 1946, the AEC emphasized military over civilian operations. In 1954, however, it began to allow private companies to develop technologies that make use of atomic energy, such as nuclear power plants. Congress abolished the commission in 1974. Its research operations were transferred to the Energy Research and Development Administration and later to the Department of Energy. A new body, the Nuclear Regulatory Commission, took over the AEC functions of licensing and regulating nuclear power plants. Richard F. Hirsh

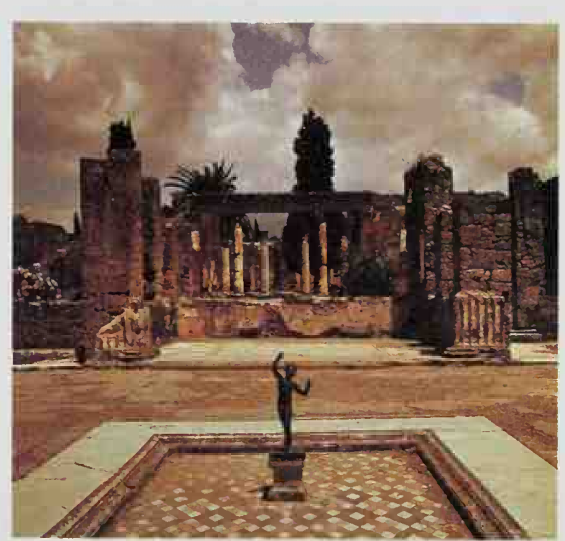
Atomism, *AT uh mihz uhm,* is a philosophical view that developed in Greece during the 400's B.C. The atomists asserted that reality consisted of two things: atoms and void. The term *atom* comes from the Greek word *atomos,* which means *uncuttable.* According to the atomists, atoms are invisible and indivisible bits of matter that are ungenerated and indestructible. They are unlimited in number and vary in size, shape, and arrangement. Atoms have come together by chance to form our world and the things in it as well as innumerable other worlds.



The atomists believed the motion of the atoms is governed by necessity. They also believed every event is the result of a series of collisions. The atomists theorized that events can be predicted in advance. The philosopher Epicurus introduced a major revision with the idea that atoms are subject to an occasional swerve. Epicurus thought the swerve broke the pattern of predetermined events and provided a basis for free will.

The atomistic philosophy was formulated by Leucippus during the second half of the 400's B.C. It was developed in detail by Democritus, taken over and modified somewhat by Epicurus, and popularized by the Roman poet Lucretius. The best source for knowledge of Greek atomism comes from Lucretius's poem *On the Nature of Things.* Carl A. Huffman

See also Democritus; Epicurus; Leucippus; Lucretius; Materialism.

Atrium, *AY tree uhm,* was the central room of early Roman houses. The atrium contained the hearth and was used for cooking, sleeping, and entertaining. A hole in the center of the roof allowed the smoke to escape. As the design of Roman houses became more advanced, the kitchen and hearth were removed to other locations. The atrium remained as a formal reception area and center of family life. Rain falling through the roof opening was caught in a central marble basin called the *impluvium.* A typical later Roman atrium was richly decorated. See Rome, Ancient (picture: A Roman house).

In later times, the word *atrium* came to refer to any open courtyard surrounded by an arcade. An atrium led to the entrance of many early Christian churches from the 300's to the 500's. See Architecture (Early Christian architecture; picture). William J. Hennessey

SCALA Art Resource

The atrium was a courtlike reception room in Roman houses. This ruined atrium was part of the House of the Faun at Pompeii.

Atrocity. See Concentration camp; Genocide; Nuremberg trials; Torture; War crime.

Atrophy, *AT ruh fee,* is the normal or abnormal shrinking of any part of the body. Some body tissues may shrink in size as a result of disease. For example, progressive muscular atrophy, a disease of a part of the spinal cord, causes certain muscles to atrophy. People with this disease lose the ability to move their arms and legs. The name *atrophy* comes from two Greek words meaning *not nourished.* Mary Frances Picciano

Atropine, *AT roh peen,* is a drug derived from several plants in the nightshade family, especially from a bushy

plant called *belladonna* or *deadly nightshade.* Physicians now also use numerous synthetic versions of atropine because they provide shorter-lasting effects and work more selectively on specific organs of the body.

Physicians use atropine and its synthetic versions during eye examinations to relax the muscles of the eye and to cause the pupil to *dilate* (expand). The drug also relieves certain types of noninfectious diarrhea and is useful as a remedy for poisoning by certain pesticides and nerve gases. A common side effect of atropine is dry mouth.

Atropine works by counteracting the effect of *acetylcholine,* a body chemical that transmits nerve impulses. The drug is extremely powerful and should never be taken without a prescription and supervision by a physician. High doses can cause *hallucinations* (seeing, hearing, or feeling things that do not exist), rapid heartbeat, and coma. Frank Welsch

See also Belladonna.

Atropos. See Fates.

Atsina Indians. See Gros Ventre Indians.

Attaché, *AT uh SHAY,* is an officer attached to a diplomatic office. The word is French for *attached.* An attaché is usually an officer of the army, navy, or air force, and is called a military, naval, or air attaché. The United States often sends officers from the Departments of Commerce, Agriculture, or Labor as attachés to an ambassador. This officer is called a commercial, agricultural, or labor attaché. Most large countries send attachés of some kind. The United Kingdom assigns scientific-research attachés to important embassies.

Cultural and social-welfare officers have attaché status. Attachés usually accompany ambassadors or other high officials on missions of state. Their duties are similar to those of secretaries. Some attachés of the U.S. government are assigned to consular offices, particularly in larger cities of the world. Most are appointed from the list of foreign-service officers in the Department of State. But many attachés with special skills and experience are selected from private industry.

Michael P. Sullivan

Attachment is the legal term for a court order to seize a person or a person's property. It was used in England so long ago that no record of its beginnings exists. Some people believe that the English got attachment from the Romans. At first, attachment provided a way of forcing a person to come to court. An officer would take the person's horse, plow, or furniture. The owner had to go to court to get these goods back. Today, attachment is used chiefly against debtors. If people leave the state, it is hard to collect any debts they left behind. But if they also leave some property, an attachment of the property will protect the person to whom the debt is owed. This person can then sue for the debt, and, if he or she wins, the attached property can be sold to satisfy the claim. In many states, the person obtaining the attachment has to put up a bond or security for payment of damages, in the event that the court later determines that there was no right to attach the property. Writs of attachment formerly were issued against people as well as goods. They now are used in this way as a rule only to seize a person who is in contempt of court.

See also Contempt; Debt; Garnishment.

James L. Winokur

Attainder, *uh TAYN duhr,* is a legal term for the loss of civil rights by an outlawed person or a person sentenced to death. According to old English law, such people lost their rights to property. Their land and personal belongings were taken from them. Because they were judged to have suffered *tainting* (corruption of blood), they could not inherit property or leave property to anyone. Parliament put an end to attainder in Britain in 1870, and now almost all countries have abolished it. In the United States, people may lose their civil rights for the crime of treason, but the Constitution (Article III, Section 3 [2]) states their punishment may not affect their families, who may inherit their property.

A *bill of attainder* is an act passed by a legislature which *attaints* some person or group and thus takes away property and civil rights without a trial. To be classified as a bill of attainder, the act must punish. Mere regulations are not considered bills of attainder. Bills of attainder are not legal in most countries. In the United States, the Constitution (Article I, Section 9 [3]) prohibits the nation or any state from passing such a bill.

After the American Civil War (1861-1865), Congress passed a law taking away the property of some people it called rebels. But the courts held that Congress could only take the rents or income from such property during the lifetime of the rebels, and could not deprive their heirs of the property. Jean Appleman

Attar, *AT uhr,* is a sweet-smelling oil obtained from rose petals. It is used to give a rose odor to perfumes. The most fragrant attar comes from a kind of red rose grown in Bulgaria and is used only in expensive women's fragrances. A less fragrant attar is taken from a white rose grown in Bulgaria. In addition, attar comes from roses grown in Ukraine, Turkey, Morocco, and France.

Producers obtain attar by placing rose petals in a tank and passing steam through them. The steam is collected in large flasks, where it cools and *condenses* (changes to a liquid). The attar floats to the top of the liquid and can then be removed. Patricia Ann Mullen

Attention deficit disorder is a behavior problem in which people have unusual difficulty paying attention, sitting still, or controlling their impulses. The formal term for attention deficit disorder is *attention-deficit/hyperactivity disorder* (ADHD). ADHD is the most common behavior problem in children. The disorder is diagnosed in boys more than twice as often as in girls. A significant number of teen-agers and adults also have ADHD.

Most experts recognize three types of ADHD. The *hyperactive-impulsive type* is also called *hyperactivity.* Children with this type of ADHD are excessively fidgety and restless. They often cannot wait their turn to speak in class or to take part in a group activity. People with the *inattentive type* of ADHD are not physically restless, but they have trouble concentrating. They are forgetful and disorganized and often fail to finish schoolwork or other tasks. The inattentive type of ADHD occurs more often in girls than does the hyperactive type. Most patients with ADHD have the *combined type,* which includes symptoms of both the hyperactive and inattentive types.

Most experts think ADHD has a physical cause that has not yet been identified. Scientists now study brain

function using *magnetic resonance imaging* and other techniques that harmlessly produce images of the living brain. Such studies show that the brains of children with ADHD differ from those of children without the condition. Some of these differences occur in regions of brain called the *frontal lobes* that control planning and setting limits on behavior. Other studies suggest that certain *genes* (the hereditary material in cells) play a role in many cases of ADHD.

Most physicians believe that certain medications help people with ADHD. The drug most often prescribed is *methylphenidate,* known by the trade name Ritalin. Ritalin and similar drugs appear to improve self-control by stimulating the parts of the brain that regulate brain activity. Children with ADHD also benefit from *behavior modification.* In this therapy, adults help children gain self-control by providing close supervision as well as frequent rewards for appropriate behavior.

Attica. See Athens.

Attila, *AT uh luh* or *uh TIHL uh* (? -A.D. 453), was a king who united the Huns, a Mongoloid people that began to invade the Roman Empire during the late A.D. 300's. Attila inherited the Hunnish kingdom, which was centered roughly in what is now Hungary. He conquered surrounding territories, until the Huns controlled a region extending from the Danube River to the Baltic Sea, and from the Rhine River to the Caspian Sea.

Attila became king in 434. He ruled jointly with his brother, Bleda, until he murdered Bleda in 445. From 435 to 439, Attila conquered many barbarian peoples in eastern and central Europe. He forced the East Roman Empire to pay him a yearly fee so he would not attack. But he looted its provinces in southeastern Europe from 441 to 443, and again in 447.

Attila then turned his attention to the West Roman Empire. In 450, he demanded Honoria, sister of Emperor Valentinian III, as his bride, and half the West Roman Empire as her inheritance. Valentinian refused. Attila stormed into Gaul (now mainly France), but a combined army of Romans and barbarians stopped him in the Battle of Châlons, near Troyes, in 451. He retreated east of the Rhine River. In 452, he invaded Italy, capturing and destroying many cities north of the Po River. But famine and disease forced his troops to withdraw. Attila died in 453, and, in time, the Huns were absorbed into the peoples of southeastern Europe.

Scholars question Attila's historical importance. He won battles only against weak enemies. Although he seriously threatened the East and West Roman empires, he was unable to win decisive victories over them. His kingdom collapsed soon after his death. Perhaps his greatest importance was his ability to unite the Huns for a short time. William G. Sinnigen

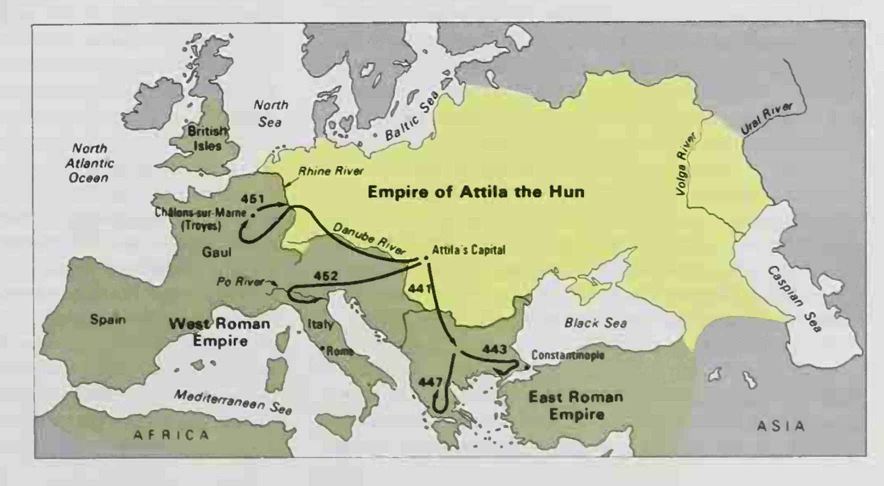
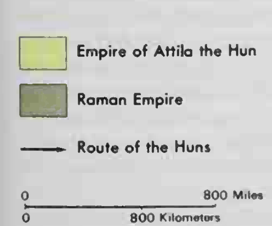
Attlee, Clement Richard (1883-1967), was the leader of the British Labour Party from 1935 to 1955. He served as prime minister of Britain from 1945 to 1951. During those years, the British government brought various industries under state ownership. It also established tax-supported health and welfare services.

Attlee was born in London. He studied at Oxford University. After four years of law practice, from 1905 to 1909, he did social-service work in the Limehouse district of London. In 1910, he became secretary of Toynbee Hall, a famous settlement center. He lectured in social science at the London School of Economics and Political Science from 1913 to 1923. In 1919 and 1920, he was mayor of the Stepney district in London.



Attlee served as a major in the British Army in World War I (1914-1918). He entered the House of Commons in 1922 as a member for Limehouse. He became leader of the Labour Party in 1935. Attlee served as Britain's deputy prime minister from 1942 to 1945 and as *lord privy seal* (the keeper of one of Britain's official seals) from 1940 to 1942. Queen Elizabeth II made Attlee an earl in 1955. Keith Robbins

Attorney. See Lawyer.



Attorney, District. See District attorney.

Attorney, Power of. See Power of attorney.

Attorney general is the chief law officer in the governments of English-speaking countries. In the United States, the attorney general is appointed by the president, with the approval of the Senate, and serves in the Cabinet. The attorney general heads the Department of Justice and represents the government in legal matters (see Justice, Department of). The responsibilities of this office include enforcing federal laws, particularly crimi-

Attila's empire stretched from the Danube River on the south to the Baltic Sea on the north, and from the Rhine River on the west to the Caspian Sea on the east. In the 400's, Attila attacked the East and West Roman empires.

WORLD BOOK map

nal statutes. Each U.S. state government has an attorney general. This official is elected by the voters in 43 states and is selected by other methods in the remaining 7. In Canada, the minister of justice may also be called the attorney general. A member of the majority party in Parliament is chosen for this post by the prime minister and is appointed by the governor general. David R. Berman

Attucks, *AT uhks,* **Crispus** (1723?-1770), was a leader of the patriot crowd that British troops fired upon in the so-called "Boston Massacre" of 1770. The British had stationed four regiments in Boston in 1768. On March 5, 1770, about 400 Bostonians surrounded a detachment of British troops and goaded them into firing. Attucks and two other men were killed instantly. Two others died later of wounds. See Boston Massacre.

Little is known of Attucks, but several historians believe he was a runaway slave of mixed black and white descent. In 1888, Boston erected a monument to honor the patriots who died in the incident. James Kirby Martin

Atwood, Margaret (1939-) is a Canadian poet, novelist, and critic. Atwood first gained recognition for her collection of poems *The Circle Game* (1966). Her many other books of poetry include *The Journals of Susanna Moodie* (1970), which is a verse biography of an early Canadian writer; *Power Politics* (1971), which is an investigation of the limits of male-female relationships; and *Two-Headed Poems* (1978), which includes poems about a mother and child. Atwood's *Selected Poems* was published in 1978, and her *Selected Poems II* was published in 1986.

Atwood gained a wide reputation as a novelist with *Surfacing* (1972), which is the story of a woman who searches in the world of nature for the meaning of her life. *The Edible Woman* (1969) is a satiric comedy about a woman whose personality is being destroyed by her relationship with her fiancé. *Lady Oracle* (1976) is a mix of social satire, psychological analysis, and fantasy. *Bodily Harm* (1981) deals with a Canadian journalist and her experiences during a revolution in the Caribbean. *The Handmaid's Tale* (1985) is a novel in which women living in the United States in the future are stripped of all rights. *Cat's Eye* (1988) is a detailed investigation of the forms of autobiography. *The Robber Bride* (1993) puckishly analyzes feminist politics by rewriting a Grimm's fairy tale. *Alias Grace* (1996) is a psychological mystery. *The Blind Assassin* (2000) is a complex family chronicle that includes a science-fiction novel within the main story. The novel won the 2000 Booker Prize, the United Kingdom's most important literary award.

Atwood's stories have been collected in *Dancing Girls* (1977), *Bluebeard's Egg* (1983), and *Wilderness Tips* (1991). Atwood's selected literary essays were collected in *Second Words* (1982). In addition, Atwood is the author of an influential book of criticism called *Survival: A Thematic Guide to Canadian Literature* (1972). Margaret Eleanor Atwood was born in Ottawa, Ontario.

Auburn University is a coeducational state university that has campuses in Auburn and Montgomery, Alabama. The Auburn campus has colleges of agriculture, business, education, engineering, liberal arts, sciences and mathematics, and veterinary medicine. It also has schools of accountancy, architecture, fine arts, forestry, home economics, nursing, pharmacy, and graduate studies. Courses lead to bachelor's, master's, and doctor's degrees.

The Montgomery campus has divisions of business, education, liberal arts, and sciences. It grants bachelor's and master's degrees.

The campus in Auburn was chartered in 1856 as the East Alabama Male College of the Methodist Church. In 1872, it became a state-supported school and was renamed Alabama Agricultural and Mechanical College. It became Alabama Polytechnic Institute in 1899 and was renamed Auburn University in 1960. The Montgomery campus opened in 1969.

Critically reviewed by Auburn University

Auchincloss, *AW kihn klahs,* **Louis** (1917-), is an American author. He ranks as one of the finest literary observers of the American "upper class" of his time.

Born in Lawrence, New York, he attended Groton, a private school; Yale University; and the University of Virginia. Auchincloss is also a lawyer with a Wall Street firm in New York City. Many characters in his novels are attorneys.

Auchincloss acknowledged the influence of authors Henry James and Edith Wharton. Like them, he sees that the traditions of family, social position, and wealth can frequently decline into snobbishness and materialism. *The Great World and Timothy Colt* (1956) shows a lawyer's desire for success and his struggle to satisfy his principles. Auchincloss's novel *The Rector of Justin* (1964) is a study of a famous headmaster of a New England prep school. Auchincloss's other novels include *I Come as a Thief* (1972), *The Partners* (1974), *The House of the Prophet* (1980), and *The Golden Calves* (1988).

Auchincloss's stories were collected in *The Winthrop Covenant* (1976), *Narcissa and Other Fables* (1983), *Skinny Island* (1987), and *The Anniversary* (1999). His essays were collected in *The Style's the Man* (1994). He described his early life in an autobiography, *A Writer's Capital* (1974).

Victor A. Kramer

Auckland, *AWK luhnd* (pop. 345,768; met. area pop. 1,109,100), is New Zealand's largest city and chief port. More than a fourth of the nation's people live in the greater Auckland region, which includes the central city and several suburbs. Auckland occupies a strip of land between Waitemata Harbour and Manukau Harbour in the country's North Island. For location, see New Zealand (political map).

Auckland is a market center for nearby agricultural and timber areas. It is also New Zealand's chief business and transportation center. Auckland's industries produce food, marine products, steel, and other items. The Auckland Harbour Bridge, which links the central city and the suburbs to the north, is an important landmark.

Auckland is known as the *City of Sails* because of the many yachts in its harbors. It has spacious parks and many beaches. Auckland's cultural institutions include the University of Auckland, the War Memorial Museum, and a number of art galleries.

New Zealand's Maori people had lived in the Auckland area for thousands of years before British settlers

Auction is a type of sale in which an item is sold to the person who bids, or offers, the most money for it. An *auctioneer* receives the bids and conducts the sale. Goods often sold at auctions include fine and decorative arts, antiques, collectibles, farm products, livestock, and real estate. Tobacco and thoroughbred horse auctions are also popular.

Many bidders set maximum price levels, often called *limits* or *stop prices*, above which they will not bid. Similarly, many sellers establish minimum price figures known as *reserves*, below which they will not sell. In an *auction with reserve*, the seller has the right to withhold an article from sale if he or she has decided that the highest bid is too low. Reserves are usually confidential and determined before the auction between the seller and the auctioneer or auction company. In an *auction without reserve*, the seller agrees to sell the article to the highest bidder regardless of the price.

Many auctioneers speak in a quick, rhythmic chant to inform participants of an item's bidding status. Some use the famous call of "Going once, going twice, sold!" to warn bidders that the end of the auction seems near. When one bidder outbids all the others—and exceeds the seller's reserve—the dropping of the auctioneer's hammer signals a sale. At this point, the final bid creates a binding contract between the seller and the highest bidder. The selling price is called the *hammer price*.

After an auction, the seller usually pays a *selling commission* and the buyer often pays a *buyer's premium* to the auctioneer or the auction company. Most auction organizations require auctioneers to have official licenses.

In the 1990's, certain computer Web sites introduced *online auctions* over the Internet. The largest and most popular auction Web site is called eBay. Online auctions closely follow the procedures of live auctions, except that bidders can enter bids from their computers at any time. Another advantage is that the Internet allows sellers to offer a wide variety of items to a vastly expanded international audience. The most reliable auction Web sites guarantee both the authenticity and the condition of their offerings. C. Hugh Hildesley

Auden, *AW duhn,* **W. H.** (1907-1973), an English-born poet, is best known for the remarkable variety of his works. He wrote ballads, blues, limericks, sonnets, nonsense verse, oratorios, free verse, *librettos* (words) for operas, and dramas. Auden won the Pulitzer Prize in 1948 for his book-length poem *The Age of Anxiety*.

Wystan Hugh Auden was born Feb. 21, 1907, in York. As a student at Oxford University, he was the leader of a group of writers. In the 1940's, he turned to Christianity and psychoanalysis as partial solutions to civilization's problems. He moved to the United States in 1939 and became a U.S. citizen. In 1972, he moved back to Oxford.

Auden collaborated with Christopher Isherwood on travel books and some symbolic and satirical plays in the 1930's, including *The Dog Beneath the Skin* (1935) and *The Ascent of F6* (1936). He helped write the libretto for Russian composer Igor Stravinsky's opera *The Rake's Progress* (1951). Many of Auden's critical essays appear in *The Dyer's Hand* (1963). William Harmon

Audiology, *aw dee AHL uh jee,* is a profession devoted to the diagnosis and treatment of hearing problems. Audiologists determine if an individual has a hearing deficiency. They also measure the effect of partial or total hearing loss on a patient's ability to communicate.

Audiologists use behavioral and electrophysiologic tests to determine a person's ability to hear. Behavioral tests measure how the person responds to a variety of sounds and vibrations. Electrophysiologic tests measure the electric activity of a person's nervous system in response to sound. Audiologists evaluate patients and fit

them for hearing aids. Some patients are also taught *speech reading* (lip reading) to supplement their use of hearing aids.

The audiologist determines the effect that a loss of hearing might have on a person's ability to handle schoolwork or a job. Language instruction and counseling help overcome problems that the hard of hearing may have when conversing with other people.

To practice audiology in the United States, a person usually must have a certificate from the American Speech-Language-Hearing Association. In some states, the person also must pass a test for a state license. Most audiologists have at least a master's degree in audiology, and many have a Ph.D. as well. College requirements for a degree in audiology include introductory courses in hearing, speech, and language.

Audiologists work in many settings. These include private offices, hospitals, clinics, community speech and hearing centers, and schools. Frank E. Musiek

See also Deafness.

Audio-visual materials, also known as *instructional media,* are educational devices that work through sight, sound, or both. Any combination of seeing and hearing information can greatly increase a person's ability to remember what he or she learns.

Teachers use a great variety of audio-visual materials. These range from simple devices, such as chalkboards, to complex technology, such as computers.

Visual materials are primarily for seeing. Such materials are often combined with talks and lectures to help listeners visualize and thus understand the information that is being presented. For example, teachers often use as visual aids pictures, maps, charts, models, or the actual objects being discussed. In addition to these common visual aids, the major forms of visual materials include (1) chalkboards and dry-erase boards, (2) flip charts, (3) projectors, and (4) film strips and slides.

Chalkboards and dry-erase boards. Chalkboards—made of slate, glass, or wood—are probably the most widely used visual aid. Accessories that are used with chalkboards include large protractors to measure angles and devices to draw the five lines of a musical staff. In addition, teachers can use patterns that are cut from cardboard to trace outlines on the chalkboard.

A *dry-erase board* is a steel surface coated with white enamel on which the user writes with special felt markers. Some dry-erase boards include a device that scans what is written on the board and makes paper copies to give to the audience.

Flip charts consist of a large pad of paper mounted on a frame. The user writes information on the pad during a presentation or prepares it beforehand to display while speaking. Material on a regular sheet of paper can be enlarged by a special machine for use on a flip chart. Business and industrial trainers frequently use flip charts.

Projectors can display both "solid" and transparent objects. An *opaque projector* is used to project materials that do not let light through. This unit can display on a screen an enlarged image of a book, document, or small object. Light from the projector lamp shines on an object, an image of which is reflected by a tilted mirror and enlarged through a lens onto the screen.

Overhead projectors are used to project *transparencies* onto a screen. The transparency is a clear plastic sheet with material printed on it. It is placed on a clear, flat surface over the projector lamp. The image on the transparency is reflected by a mirror and through a lens onto the screen.

Transparencies can be made by several methods, including drawing or writing on a clear plastic sheet. They may also be made on a special machine that copies printed material onto a sheet of plastic film, which becomes the transparency. Transparencies can also be made using a photocopying machine. Computer designs of graphs, charts, and drawings can be printed out as transparencies by a laser printer.

Color transparencies can be made using photography or a color photocopying machine. A *thermal-wax color printer* connected to a computer can make transparencies of an image designed on the computer. The printer has a roll of clear plastic coated with wax in four colors. The printer melts the wax onto specially treated paper that absorbs some colors but leaves an image remaining on the plastic.

A *liquid crystal display* (LCD) unit that connects to a computer creates what may be thought of as an electronic transparency. The LCD panel has a thin layer of a substance called *liquid crystal,* which changes color when an electric charge is applied to it. The panel picks up and displays an image of what appears on the computer screen. The LCD panel is placed on an overhead projector to be projected onto a screen. LCD panels may be colored or black-and-white. LCD units are convenient because they save the step of making a transparency and because computer images can be changed and updated easily. LCD panels are also lightweight and inexpensive.

Filmstrips and slides. A filmstrip is a strip of 35-millimeter film with a series of related still images that are displayed by a projector. Filmstrip projectors can be controlled by hand or electrically by remote units. A record player or tape recorder attached to the projector may provide sound for the filmstrips. Some projectors have built-in tape players, and some cassette tapes have a signal recorded on them that advances the filmstrip automatically.

A 35-millimeter slide projector is used to show slides, which are individual transparent photographs. A person can take pictures to develop into slides by using a 35-millimeter camera. Slides are arranged in a tray from which they individually drop between the light and the lens that projects them. Slides are easily removed from a tray and rearranged to create different slide shows. Most slide projectors have a remote control device that enables the presenter to manage the show from anywhere in the room. Slide projectors are sometimes used with or connected to tape players to add sound to a slide show.

A device called a *dissolve unit* allows two or more slide projectors to work together. The unit causes the image from one slide to fade out while another picture fades in on the same screen. As many as 100 or more projectors with dissolve units can be worked together through the use of an *interface programmer board,* an electronic device that plugs into a computer. A computer program directs signals through the board to control the slide equipment. Museums, tourist centers, and sales conventions often use such slide presentations.

Teachers can use *computer graphics* to develop slide shows. Computer graphics is a term that refers both to the use of computers to create pictures and to the pictures themselves. See **Computer graphics**.

Audio materials are primarily for hearing. They include phonograph records, audio cassette tapes, audio compact discs (CD's), and the machines on which they are played. These materials are used to listen to music, stories, poetry readings, dramatic performances, and speeches. With tape recorders, students can record and listen to themselves. Music and foreign-language students, for example, often record themselves as they practice speaking or singing. They can then play the tape to hear how well they did. People also record lectures to review later.

Multisensory materials are designed for both seeing and hearing. A filmstrip or slide projector combined with an audiotape is an example of a simple multisensory medium. More sophisticated multisensory aids include motion pictures, computers, and telecommunication equipment.

Motion pictures. Films, especially 16-millimeter films, were once a major instructional tool. Videotapes are now more common. Videotape is easier to use, more durable than film, and less expensive. Videocassettes are a common form of videotape used in schools. Videocassette recorders (VCR's) play back the tapes, which students usually view on television sets. However, TV sets can be too small for a large audience to see. *Video projectors* can play a videotape by projecting a large image onto a screen. Some video projectors can work with computers to display output from computer programs.

A *videodisc* is a flat, round platter that is played on a videodisc player. The player uses a laser to convert the pictures and sounds recorded on the videodisc into TV signals. The clarity of the TV image provided by videodisc is superior to that of videotape.

There are three levels of videodisc players. *Level 1* allows only the playback of the material. *Level 2* enables the viewer to quickly seek and select different parts of the disc to view. *Level 3* players are linked to a computer. These players permit the user to interact with the video. For example, a student can answer a test question and have the disc respond automatically.

Many schools have a video-production system, which includes equipment to tape and play back videos. More sophisticated systems have cameras, editing equipment, and audio equipment. They may also have computer graphics devices to create visual effects in producing videos. School video-production systems are used by teachers to produce educational material as well as by students learning to work with television.

Computers are a major new force in education. Originally, they were used only as an addition to regular learning programs, such as for a mathematics drill. However, the sophistication of instructional computer programs has increased. Students can now use computer tutorials that check their answers and provide additional help if the student gives a wrong answer. In addition, some publishers have begun offering electronic books, also called *e-books,* that present textbook information through computers.

Computer *simulations* (representations that respond to changing conditions) enable students to experience realistic situations. For example, pilots in training use *flight simulators,* which imitate an airplane in flight. Computer simulations can also be used by an entire class. The scene for the simulation may be projected onto a screen for the class to see. The computer manages the input and output, while the class tries to work through the situation presented in the simulation. For example, one simulation program presents political problems facing a mayor and city council. Another program involves city planning, and one used in a biology class portrays the activities in an ant colony. An advantage of these programs is that a whole class can use one computer, which is less costly for schools than providing individual computers.

Multimedia is the most recent development in education and training. It is the combination of computers, sound, and visuals to create an instructional package.

Telecommunication equipment is used to transmit and receive information over long distances. Modern telecommunication systems have allowed a development in instructional media known as *distance education.* Distance education involves the use of satellites or cable TV to transmit a lecture or other educational presentation to many locations. This enables many schools to share a class taught by one teacher. Distance education provides many students with instruction that would not be available to them otherwise. For example, a small college with limited resources could show on television a class taught by a well-known professor at a large university. Carl W. Stafford

Audit is a systematic and official examination and check of business activities. The activities may be those of a public or private organization. Such organizations rely on audits to provide independent and expert business advice. A person who conducts an audit is called an *auditor.* There are three basic types of audits—*financial, compliance,* and *operational.*

A financial audit checks the reliability of financial information. One important kind of financial audit is a financial statement audit. The auditor, usually a certified public accountant (CPA), inspects the accounting records to decide whether the financial reports reflect generally accepted accounting principles. The Financial Accounting Standards Board establishes these accounting principles. In a financial audit, the procedures used by a CPA are based on auditing standards that have been established by the American Institute of Certified Public Accountants. All corporations that have publicly traded securities in the United States are required to have a financial audit.

A compliance audit determines if an organization has followed internal policies, laws, regulations, and contracts. Operational audits deal with some aspect of an organization's operations. These audits are concerned with the efficient use of economic resources and the achievement of stated goals. Operational audits are intended to help an organization become more productive and more profitable.

The word *audit* comes from the Latin word *auditus,* meaning a *hearing.* Auditing began in ancient times. However, modern auditing techniques originated in Britain during the mid-1800's. At that time, the main purpose of an audit was to detect fraud. Richard P. Brief

Auditory canal. See Ear (The outer ear; diagrams).

Audubon, *AW duh BAHN,* **John James** (1785-1851), was one of the first people to study and paint the birds of North America. Audubon's lifelike paintings of birds in their natural surroundings brought him fame and fortune.

His life. Audubon's diaries and letters created a mystery about his background and parentage, but records indicate that he was born on April 26, 1785, at Les Cayes, Santo Domingo (now Haiti). His mother, a Creole of Haiti, died soon after his birth. Records show that the boy, known as Jean Rabin, was taken to France by his father, Jean Audubon, a French sea captain.

Audubon and his wife legally adopted the boy when he was 8 years old. These records disprove claims by Audubon's descendants, derived from passages in his diaries and letters, that Audubon was the Lost Dauphin of France.

In 1803, Captain Audubon sent the youth to live on an estate called Mill Grove near Philadelphia. There, young Audubon spent much time drawing birds. He and Ferdinand Rozier opened a general store in Louisville, Kentucky, in 1807. Audubon married a Mill Grove neighbor, Lucy Bakewell, the next year. He failed in several business ventures. While Rozier conducted their business, Audubon wandered through the countryside looking for birds. His business career ended in 1819 when he was jailed for debt. He entered a plea of bankruptcy to gain his freedom.

Courtesy of the New-York Historical Society, New York City

An Audubon painting of passenger pigeons shows the realistic, colorful style of the artist and naturalist. John James Audubon published this water color in 1829.

In 1820, Audubon conceived the idea of publishing a collection of paintings of North American birds. His family followed him to Louisiana, where he painted birds in their natural surroundings. His wife worked as a governess and teacher to support the family. Audubon drew portraits and taught music and drawing.

His works. Unable to find an American publisher, Audubon went to England and Scotland in 1826. His pictures created a sensation, and he published *Birds of America* (1826-1838), which was a work of 87 parts containing 435 life-sized, colored engravings made from his water colors. Audubon and William MacGillivray, a Scottish naturalist, wrote a text, *Ornithological Biography* (1831-1839).

Audubon returned to the United States in 1839 and published American editions of his bird paintings. Later, Audubon worked with John Bachman on *The Viviparous Quadrupeds of North America* (1842-1854). Audubon made his last collecting trip, along the Missouri River, in 1843. He died on Jan. 27, 1851. Donald F. Bruning

Audubon Society, *AW duh* BAHN, **National,** is one of the oldest and largest national conservation organizations in the world. It was founded in 1905 and named for the American bird artist and naturalist John James Audubon. The society is dedicated to the long-term protection of wildlife and of land, water, and other natural resources; the protection of life from radiation, toxic substances, and other pollutants; and the easing of global problems caused by overpopulation and the depletion of natural resources.

The National Audubon Society has about 625 chapters and affiliated clubs and 10 regional offices. It also maintains a legislative center in Washington, D.C. Its nationwide sanctuary system protects over 250,000 acres (101,000 hectares) of wildlife habitat and many endangered species. The society conducts research on wildlife and environmental issues. Audubon ecology camps in Connecticut, Maine, Wisconsin, and Wyoming offer summer sessions for adults, children, and families. Education centers in Connecticut, California, Ohio, and Wisconsin provide training for naturalists and outdoor programs for the public. Audubon Adventures is a popular environmental education program for youngsters.

The society publishes *Audubon,* a magazine; *American Birds,* a scholarly journal; and the *Audubon Activist,* a newspaper on environmental issues. The National Audubon Society's headquarters are in New York City.

Auer, *OW uhr,* **Leopold** (1845-1930), a Hungarian violinist, became one of the most famous violin teachers of his time. Auer inaugurated a new method of violin playing and bow technique. From 1868 to 1917, he was a professor at the St. Petersburg Conservatory in Russia. Among Auer's famous students were Mischa Elman, Jascha Heifetz, and Nathan Milstein. Auer wrote about his teaching methods in *Violin Playing as I Teach It* (1921) and *Violin Masterworks and Their Interpretation* (1925). He also wrote an autobiography, *My Long Life in Music* (1923). Auer was born in Veszprém. Stephen Clapp

Auerbach, *OW uhr bahk,* **Red** (1917-), was one of the greatest coaches in the history of the National Basketball Association. During his 20 years as a professional basketball coach, his teams won 938 regular-season games. This total stood as a league record until it was broken by Lenny Wilkens during the 1994-1995 season.

Auerbach coached the Boston Celtics from the 1950-1951 season through the 1965-1966 season. He led the Celtics to nine NBA championships, eight in a row from the 1958-1959 season through the 1965-1966 season. In 1966, he retired as Celtics coach and became the team's president and general manager. He retired as general manager in 1984 but remained as the team's president until 1997, when he became a vice president.

Arnold Jacob Auerbach was born in the Brooklyn borough of New York City. He began his professional career in 1946, coaching the Washington Capitols for three seasons. He coached the Tri-Cities Blackhawks for a season before joining the Celtics. Bob Logan

Augsburg, *AWGZ burg* or *OWKS boork* (pop. 250,197), is a commercial and industrial city in southern Germany. For location, see Germany (political map). Augsburg is known for its well-preserved medieval and Renaissance buildings. Its many landmarks include the Augsburg Cathedral, which dates from the 900's, and the town hall, completed in 1620. A number of beautiful Renaissance buildings stand on Maximilianstrasse and Karolinenstrasse, two famous streets in the city center. Factories in Augsburg manufacture such products as chemicals, electronics, machinery, and textiles.

The Romans founded Augsburg in 15 B.C. and later made it a provincial capital of their empire. The city became a thriving commercial and trade center during the Middle Ages. Protestant and Roman Catholic leaders met in Augsburg in 1530 to try to settle their differences (see Augsburg Confession). During World War II (1939-1945), Allied bombing damaged much of the city. The damaged areas were soon rebuilt. John W. Boyer

Augsburg Confession, *AWGZ burg* or *OWKS boork,* was a short summary of the religious teachings of Martin Luther. It was written mainly by Philipp Melanchthon, Luther's chief associate in starting and leading the Protestant Reformation. The confession was prepared in 1530 for Charles V, the Holy Roman emperor. It was named for Augsburg, Germany, scene of a *diet* (meeting) called by Charles to end religious divisions within the Empire.

Melanchthon wrote the confession to prove that Lutherans supported the historic tradition of the Christian church. He tried to compromise on some controversial issues, hoping for the reunification of Christendom. Luther, who was not permitted to attend the diet, admired the confession for "treading lightly" over disputed issues, but insisted that no more concessions be made. But it was too Protestant in tone for the emperor, and he rejected it. Melanchthon continued to make changes to the confession over the years, and conservative Lutherans objected to the altered versions. The original version became the basic statement of faith of the Lutheran Church. M. U. Edwards

See also Luther, Martin; Melanchthon, Philipp; Reformation (picture).

Augur, *AW guhr,* was the title given to priests in ancient Rome who interpreted signs, such as thunder and lightning, the flight and cries of birds, and the movement of snakes and mice. Romans believed that the gods revealed their wishes through these signs. Augurs did not predict the future. Instead, they read the signs to see if the gods approved of human actions. Augurs wore a *trabea* (white garment with a purple border).

Roman officials sought the advice of augurs before beginning elections, wars, and other important public activities. The officials might delay or cancel great ventures if the augurs reported unfavorable signs. Because augurs controlled the doctrine and practice of interpreting signs, they had great power in Roman politics.

Early Rome had three augurs, all from the *patrician* (aristocratic) class. By the late Roman Republic, the priesthood had 16 members, both patricians and *plebeians* (commoners). C. J. Bannon

See also Omen; Oracle.

August is the eighth month of the year according to the Gregorian calendar, which is used in almost all the world today. The Romans called the month *Sextilis,* which means *sixth.* They later renamed it in honor of the emperor Augustus. During Augustus's reign, the Roman Senate lengthened the month to 31 days by taking a day from February.

The first Monday in August is Emancipation Day in much of the Caribbean. In Barbados, it is also called Kadooment Day. On this day and the weeks leading up to it, people in Barbados combine a celebration of the end of the sugar cane harvest with the commemoration of the abolition of slavery. The holiday is observed with parades, music, feasting, and dancing. Native American harvest celebrations called green corn dances often fall in August.

Lammas Day, August 1, is an ancient British festival. This celebration of the harvest became associated with the Christian Church, and loaves of bread made from the season's first grains were taken to church to be blessed. The Feast of the Assumption, August 15, is celebrated by Roman Catholic and Eastern Orthodox churches. It is based on the belief that the Virgin Mary was taken up to heaven in body and soul. The feast may be related to harvest festivals of pre-Christian times. In parts of Europe, it is called the Feast of Our Lady of the Harvest.

In Nepal, Gokarne Aunsi (Father's Day) usually falls in

Important August events

1 National Day, Switzerland.
— William Clark, American explorer, born 1770.
— Francis Scott Key, American lawyer and author of "The Star-Spangled Banner," born 1779.
— Richard Henry Dana, Jr., American author, born 1815.
— Maria Mitchell, American astronomer, born 1818.
— Herman Melville, American author, born 1819.
— Colorado became the 38th U.S. state, 1876.
— Germany declared war on Russia, World War I, 1914.
— U.S. Congress passed the Atomic Energy Act, providing for civilian control of nuclear energy, 1946.
2 First United States census began, 1790.
— John Tyndall, British physicist, born 1820.
— First Lincoln penny issued in United States, 1909.
3 Christopher Columbus set sail from Palos, Spain, on his first voyage across the Atlantic, 1492.
— Ernie Pyle, American newspaper columnist, born 1900.
4 German American publisher John Peter Zenger acquitted of libel in 1735, helping to establish American freedom of the press.
— Percy Bysshe Shelley, English poet, born 1792.
5 Independence Day, Jamaica.
— Guy de Maupassant, French novelist and short-story writer, born 1850.
— Union forces won the Battle of Mobile Bay in the American Civil War, 1864.
6 Daniel O'Connell, Irish patriot, born 1775.
— The Holy Roman Empire came to an end, 1806.
— Alfred, Lord Tennyson, English poet, born 1809.
— Bolivia became independent in 1825.
— Alexander Fleming, British discoverer of penicillin, born 1881.
— Gertrude Ederle became the first woman to swim the English Channel, 1926.
— Atomic bomb dropped on Hiroshima, Japan, 1945.
7 Louis S. B. Leakey, Kenyan anthropologist, born 1903.
— Ralph J. Bunche, American statesman, born 1904.
— United States troops landed on Guadalcanal in the Solomon Islands in World War II, 1942.
8 Sara Teasdale, American poet, born 1884.
— Marjorie Kinnan Rawlings, American novelist, born 1896.
— Ernest Orlando Lawrence, American physicist, born 1901.
9 Izaak Walton, English author, born 1593.
— John Dryden, English poet and dramatist, born 1631.
— Richard M. Nixon became first U.S. president ever to resign from office, 1974.
10 The *Columbia* completed the first voyage around the world by an American ship, 1790.
— Missouri became the 24th U.S. state, 1821.
— Smithsonian Institution founded, 1846.
— Herbert Hoover, 31st U.S. president, born 1874.
11 Gifford Pinchot, American conservationist and statesman, born 1865.
12 Julius Rosenwald, American philanthropist, born 1862.
— George Bellows, American artist, born 1882.
— The United States annexed Hawaii, 1898.
13 Spanish conquerors won Mexico City from the Aztec, 1521.
— Lucy Stone, American women's rights leader, born 1818.
— Annie Oakley, American sharpshooter, born 1860.
— East Germans began building the Berlin Wall, 1961.
14 John Galsworthy, English novelist, born 1867.
— U.S. Social Security Act approved, 1935.
— The Atlantic Charter was made public, 1941.
— Pakistan became independent, 1947.
15 Napoleon Bonaparte born 1769.
— Sir Walter Scott, Scottish author, born 1771.
— Indians attacked soldiers and settlers of Fort Dearborn (now Chicago) in 1812.
— Panama Canal opened to traffic, 1914.
— India became independent in 1947.
— South Korea was established in 1948.
— Congo (Brazzaville) became independent in 1960.
16 Patriots defeated the British in the Battle of Bennington in the American Revolution, 1777.

Aug. birthstone—sardonyx

Aug. flower—poppy

Aug. 6—first woman to swim English Channel

Aug. 6—atomic bomb dropped on Hiroshima

August or early September. Fathers, both living and dead, are honored on this day.

August flowers are the poppy and gladiolus. August gemstones are the sardonyx and peridot.

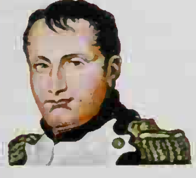
Carole S. Angell

Quotations

The brilliant poppy flaunts her head
Amidst the ripening grain,
And adds her voice to swell the song
That August's here again.
Helen Maria Winslow

All the long August afternoon,
The little drowsy stream
Whispers a melancholy tune
As if it dreamed of June,
And whispered in its dream.
William Dean Howells

Dry August and warm
Doth harvest no harm.
Thomas Tusser



If the twenty-fourth of August
be fair and clear,
Then hope for a prosperous Autumn that year.
John Ray, English Proverbs

Important August events

17 Indonesia declared independence in 1945.
— Davy Crockett, American frontiersman, born 1786.
— United States and Canada arranged for joint defense of North America, 1940.
18 Virginia Dare, first English child born in America, born 1587.
— Meriwether Lewis, American explorer, born 1774.
— Marshall Field, American merchant, born 1835.
19 The British warship *Guerrière* surrendered to the U.S.S. *Constitution* in 1812, during the War of 1812.
— Bernard Baruch, American financier and statesman, born 1870.
— Orville Wright, pioneer American aviator and airplane designer, born 1871.
— Manuel Quezon, first president of the Commonwealth of the Philippines, born 1878.
— Philo T. Farnsworth, American inventor who discovered a system for electronic television, born 1906.
— Bill Clinton, 42nd U.S. president, born 1946 in Hope, Ark.
20 Bernardo O'Higgins, Chilean patriot, born 1778.
— Oliver Hazard Perry, American naval officer, born 1785.
— Benjamin Harrison, 23rd U.S. president, born 1833.
21 Lincoln-Douglas debates began in United States, 1858.
— Hawaii became the 50th U.S. state, 1959.
22 John Fitch successfully demonstrated his side-paddle steamboat, 1787.
— The *Savannah,* first steamship to cross the Atlantic, launched 1818.
— Claude Debussy, French composer, born 1862.
— Clara Barton founded first local chapter of the American National Red Cross, 1881.
23 Baron de Cuvier, French naturalist, born 1769.
— Edgar Lee Masters, American poet and biographer, born 1869.
24 Massacre of St. Bartholomew's Day began in Paris, 1572.
— William Wilberforce, British statesman and crusader against slavery, born 1759.
— British troops captured Washington, D.C., and burned the Capitol and the White House in 1814, during the War of 1812.
25 Bret Harte, American author of stories about the Western United States, born 1836.
— Leonard Bernstein, American composer, conductor, and pianist, born 1918.
26 Antoine Lavoisier, French chemist, born 1743.
— Lee De Forest, American inventor, born 1873.
— Ottmar Mergenthaler received a patent for his Linotype machine, 1884.
— Amendment 19 to the U.S. Constitution, giving women the right to vote, proclaimed 1920.
27 Georg Wilhelm Friedrich Hegel, German philosopher, born 1770.
— Commercial oil production began in the United States when Edwin Laurentine Drake struck oil, 1859.
— Theodore Dreiser, American novelist, born 1871.
— Lyndon B. Johnson, 36th U.S. president, born 1908.
28 Spanish explorers landed in Florida where St. Augustine now stands, 1565.
— Johann Wolfgang von Goethe, German poet and dramatist, born 1749.
— The United Kingdom ended slavery in its colonies, 1833.
— More than 200,000 civil rights demonstrators staged a march on Washington, D.C., 1963.
29 Oliver Wendell Holmes, American physician and man of letters, born 1809.
— Charles F. Kettering, American inventor and automobile pioneer, born 1876.
30 Mary Wollstonecraft Shelley, English author of *Frankenstein,* born 1797.
— Second Battle of Bull Run, or Manassas, ended in Confederate victory, American Civil War, 1862.
— Ernest Rutherford, British physicist, born 1871.
— Huey Long, American political leader, born 1893.
31 Federation of Malaya (now part of Malaysia) became independent, 1957.
— Queen Wilhelmina of the Netherlands born 1880.

Augusta, *aw GUHS tuh,* Georgia (pop. 199,775; met. area pop. 477,441), lies on the state's eastern boundary, about 125 miles (201 kilometers) from the mouth of the Savannah River. Augusta's metropolitan area includes nearby Aiken, South Carolina. See **Georgia** (political map).

Augusta's chief industries produce brick, detergents, fertilizer, food products, golf carts, hospital products, newsprint, paper products, and textiles. Augusta is on the eastern edge of one of the world's greatest kaolin belts. Several plants near Augusta process kaolin, a white clay used for making fine pottery and as a coating on high-quality paper. Nearby Fort Gordon, a United States Army training center, has a larger payroll than that of the combined industries of metropolitan Augusta (see **Fort Gordon**). The city is a medical center and has several large hospitals. It is the home of Augusta State University, Paine College, and the Medical College of Georgia. The Masters Tournament, one of the world's major golf competitions, is held every spring at the Augusta National Golf Course.

James Oglethorpe, who founded the Georgia colony, ordered Augusta established in 1736. The Georgia legislature made Augusta capital of the state from 1786 to 1795. During the American Civil War (1861-1865), Augusta served as ordnance center of the Confederacy. It is the seat of Richmond County and has a mayor-council form of government. James O. Wheeler

Augusta, *aw GUHS tuh* (pop. 18,560), is the capital of Maine. It lies on both sides of the Kennebec River in the central part of the state (see **Maine** [political map]).

Augusta's major buildings include the State Capitol; other state buildings; the Maine State Library; the governor's residence, called Blaine House; and Fort Western, a restored colonial-era fort. The University of Maine has a campus in Augusta. The state government is the city's largest employer. Other employers include health-care services, an electronic equipment assembly plant, and a steel plant.

In 1628, Pilgrims from Plymouth Colony in Massachusetts established a trading post on the site of Augusta, then an Indian village called *Cushnoc.* Beginning in the 1660's, Indian wars brought trade in the area to a halt. Fort Western was built on the site of the old trading post in 1754. The settlements that grew up around the fort were then part of the present town of Hallowell. In 1797, Augusta became a separate town. It replaced Portland as the capital of Maine in 1832, because of its more central location. Augusta has a council-manager form of government. It is the seat of Kennebec County.

Patty Ammons

Augustan Age. See **Augustus; England** (The Augustan Age); **English literature** (The Augustan Age); **Latin literature** (The Augustan Age).

Augustine, *AW guh STEEN* or *aw GUHS tihn,* **Saint** (354-430), was one of the greatest leaders of the early Christian church. His writings had a strong influence on medieval religious thought. Augustine's ideas also appeared in the teachings of John Calvin, Martin Luther, and other Protestant reformers. He influenced such philosophers as Immanuel Kant and Blaise Pascal.

His life. Augustine was born Nov. 13, 354, in Tagaste, a city near what is now Constantine, Algeria. His name in Latin was Aurelius Augustinus. His mother, Saint Monica, was a devout Christian. His father was a pagan. As a young man, Augustine pursued worldly success and was attracted to several non-Christian movements. He described his early life and spiritual struggles in *Confessions,* one of the first great autobiographies.

In the early 380's, Augustine taught rhetoric in Carthage and Rome and then in Milan, Italy. Some friends in Milan encouraged him to read the works of the Greek philosophers called *Neoplatonists* (see **Neoplatonism**). These writings and the sermons of Saint Ambrose, the bishop of Milan, helped him overcome the intellectual obstacles to accepting Christianity. In 386, Augustine decided to devote himself to the faith, and Ambrose baptized him the next year.

Soon afterward, Augustine returned to Tagaste, where he organized a community of believers. In 391, he traveled to nearby Hippo. The Christian congregation there persuaded him to stay. He was ordained as a priest in Hippo in 391. From 396 until his death, he served as bishop of Hippo.

His beliefs can be divided into three main groups: (1) God and the soul, (2) sin and grace, and (3) the church and the sacraments.

God and the soul. Augustine's study of Neoplatonism convinced him that God is present in the soul of every human being. He believed that people should direct their attention to God and not be distracted by the cares and pleasures of the world.

Sin and grace. Augustine preached that people could not change their sinful ways unless helped by the grace of God. He believed that God chooses only certain individuals to receive His grace. This belief forms part of a doctrine called *predestination* or *election.*

The church and the sacraments. Augustine believed that people could not receive God's grace unless they belonged to the church and received the sacraments. A group of clergymen in northern Africa said grace could not be given unless the clergy itself was perfect. But Augustine declared that God could bypass human weaknesses through the sacraments. Augustine's book *The City of God* presents the history of humanity as a struggle between people who depend on God and those who rely on themselves. David B. Burrell

Augustine of Canterbury, *AW guh STEEN* or *aw GUHS tihn,* **Saint** (? -604), was the apostle to the English nation and the first archbishop of Canterbury. He was formerly *prior* (head) of the monastery of Saint Andrew in Rome. Pope Gregory I called him to lead a band of missionaries to England. The group landed in 597 on the island of Thanet, southeastern England. They were welcomed by Ethelbert, king of Kent. The preaching of Augustine and his missionaries turned thousands of the English to Christianity, including the king. The pope made Augustine archbishop of Canterbury in 601. Augustine's feast day is May 26 in England and Wales and May 28 in other parts of the world. William J. Courtenay

Augustus, *aw GUHS tuhs* (63 B.C.-A.D. 14), meaning *the exalted,* was the name given Gaius Julius Caesar Octavianus (Octavian) when he became the first Roman emperor in 27 B.C. The period of the Roman Republic ended, and the era of the Roman Empire began under Augustus.

Augustus' influence was so far-reaching that it lasted, and even increased, for nearly 200 years. Rome achieved great glory during Augustus' reign, and the period came to be known as the *Augustan Age.* This period was the golden age of Roman literature and architecture. Such famous writers as Virgil, Horace, Ovid, and Livy lived during this time, under the patronage of the emperor. Augustus himself was a writer, known for his simple and direct style.

Many roads, bridges, aqueducts, and beautiful buildings were built in Rome under Augustus. He boasted that he "found Rome brick and left it marble." He not only completed buildings left unfinished by Julius Caesar, but also restored many structures, including 82 temples. Sculptors created many beautiful works in a classic style to decorate his buildings.

WORLD BOOK map

The Roman Empire under Augustus expanded greatly. The yellow area above shows the empire when Augustus became emperor. He added the area shown in shaded yellow.

Octavian was born in Rome. He took the name Gaius Julius Caesar Octavianus in 44 B.C., after his great-uncle, Julius Caesar, was murdered. Caesar adopted Octavian in his will and made the 19-year-old youth his heir. Octavian returned to Rome from Apollonia, in what is now Albania, to claim his inheritance. The orator Cicero helped him legalize his adoption over the objections of Mark Antony, Caesar's chief lieutenant, who had seized Caesar's papers and money.

Rise to power. Antony controlled Rome after Caesar's death. But Octavian raised an army of Caesar's veterans and defeated Antony in northern Italy in 43 B.C. Octavian forced the Senate to elect him one of the two *consuls* (chief government officials) of Rome. He reached an agreement with Antony, and they with Marcus Lepidus (? -13 B.C.), a Roman general, formed the Second Triumvirate. They killed more than 2,000 enemies, including Cicero, who had befriended Octavian but was hated by Antony.

Octavian and Antony led an army against Brutus and Cassius, the conspirators who had murdered Caesar. Thanks to the generalship of Antony, the army defeated the murderers at Philippi, in Macedonia, in 42 B.C. Octavian became ruler of the western provinces, and Antony of the eastern provinces. The weak Lepidus was assigned to Africa, but Octavian soon forced him to retire. Another enemy of Octavian, Pompey the Younger, had gained control of Sicily. However, Pompey was defeated in 36 B.C. by Marcus Agrippa, Octavian's general and chief adviser.

In 40 B.C. Antony married Octavia, sister of Octavian, but he deserted her later for Cleopatra, queen of Egypt. The Romans feared and hated Cleopatra. When Antony gave Roman provinces to his children by her, Octavian went to war against Antony and Cleopatra. In 31 B.C., Agrippa, who was also an admiral, defeated the combined fleets of Antony and Cleopatra at Actium, on the west coast of Greece. Within a year, Antony and Cleopatra committed suicide.

In 27 B.C., the Senate voted Octavian the name *Augustus.* It also gave him legal power to direct Rome's religious, civil, and military affairs, with the Senate as an advisory body.

Achievements. Augustus restored peace and order after 100 years of civil war. He maintained honest government, a sound currency system, and free trade among the provinces. He developed an efficient postal system, improved harbors, and established colonies. He extended the elaborate highway system that connected Rome to remote parts of the empire.

Augustus gave control of the empire's more peaceful provinces to the Senate. But he kept control of frontier provinces that needed protection or pacification, and

Vatican Museums (SCALA/Art Resource)

Augustus was the first Roman emperor. This statue was made by an unknown sculptor who lived during Augustus' reign.

maintained a standing army for this task. He also kept a standing navy in the Mediterranean Sea and a small bodyguard in Rome known as the *Praetorian Guard.*

Expansion. Augustus expanded the empire, but he was more interested in peace than in war. He fought only when necessary. Augustus's generals Agrippa and Tiberius won victories in Spain, Gaul (now mainly France), and in Pannonia and Dalmatia (now parts of Hungary and Croatia). Augustus annexed Egypt and pacified Spain, Gaul, and most of southeastern Europe up to the Danube River.

In A.D. 9, his army was destroyed by Germans at the Battle of Teutoburg Forest, in what is now Germany. As a result, the Roman frontier in Germany was pushed back from the Elbe River to the Rhine River.

Augustus was a cold, calculating statesman, but he knew how to win affection. After his death on Aug. 19, A.D. 14, the people of the Roman Empire worshiped him as Divine Augustus. The remains of his tomb and many of his buildings stand in Rome. Mary Francis Gyles

Auk, *awk,* is the name of a family of sea birds that includes dovekies, guillemots, murres, and puffins. Auks are also known as *alcids.* There are 22 living species of auks. They live in the North Pacific, North Atlantic, and Arctic oceans. Auks look and behave somewhat like penguins. However, unlike penguins, auks can fly.

Like penguins, auks are excellent underwater swimmers. They propel themselves rapidly through the water with their strong wings, steering with their webbed feet.

Jacana
A dovekie, like most other auks, has black and white feathers. Auks live in the northern half of the world. They make their homes at sea and on rocky islands.

Hand-colored aquatint (1834-1836) by John James Audubon; National Audubon Society Library
Great auks were flightless marine birds of the Northern Hemisphere. Sailors in search of food on long voyages killed thousands of the birds. By the mid-1800's, great auks were extinct.

Auks feed on fish and other marine animals. They catch their food by chasing it in the water.

Auks have thick bodies and short legs. They range in size from 6 to 30 inches (15 to 75 centimeters) long. Most auks have black and white feathers. Some have gray feathers. Certain species, including guillemots and puffins, have brightly colored legs and feet. Puffins also have brightly colored bills during the breeding season.

Auks spend all the year except the breeding season at sea. They tend to nest in colonies of thousands of birds on rocky islands and return to the same nesting sites every year. Most make their nests among rocks, in burrows in the ground, or on ledges of cliffs. The female lays one or two eggs, which hatch in 3 to 6 weeks.

The *great auk,* also called the *garefowl,* is an extinct member of the auk family. About the size of a goose, this bird was the largest auk and could not fly. Hunters killed the last great auks in 1844. Donald F. Bruning

Scientific classification. Auks make up the family Alcidae. The great auk is classified as *Pinguinus impennis.*

Auld Lang Syne, *AWLD lang SYN,* is a traditional song of friendship in the English-speaking world. The title means *old long since,* or *days gone by,* in Scottish dialect. The Scottish poet Robert Burns is usually given credit for the song's words, but he probably based them on a folk song. The melody is a version of an old Scottish tune. "Auld Lang Syne" is a traditional New Year's Eve song in the United States. Valerie Woodring Goertzen

Aung San Suu Kyi, *awng sahn soo chee* (1945-), leads the opposition to the military dictatorship that rules Myanmar, formerly called Burma. She won the 1991 Nobel Peace Prize for her nonviolent efforts to restore democracy to her country.

Aung San Suu Kyi first became involved in her nation's politics in 1988, after the dictatorship killed thousands of protesters. That year, she cofounded and became secretary general of the National League for Democracy (NLD), soon the main opposition party in Myanmar. The NLD won a landslide victory in national elections held by the military in 1990. But the military refused to recognize the election results and began to arrest members of the NLD. Aung San Suu Kyi was held under house arrest from 1989 to 1995. After her release, she continued working to bring democracy to Myan-

mar, though the military government restricted her freedom of travel. The military again confined her to her home from September 2000 to May 2002.

© Candace Scharsu, Archive Photos

Aung San Suu Kyi

Aung San Suu Kyi was born on June 19, 1945, in Yangon. Her father, Thakin Aung San, was the founder of independent Burma. Aung San Suu Kyi studied in Burma and India and graduated from Oxford University in 1967. She is the author of several books, including *Freedom from Fear and Other Writings* (1991). James F. Guyot

Aurangzeb, *AWR uhng ZEHB* (1618-1707), was an emperor who ruled what is now India and Pakistan from 1658 until his death. His reign as monarch of the Mughal Empire was marked by wars of expansion in southern India and wars to put down rebellions in the north. Aurangzeb, a devout Muslim, tried to make all his people follow Islam, the Muslim religion. He placed special taxes on Hindus, who made up the majority of the population, and destroyed Hindu temples and images. Aurangzeb also destroyed many works of art because he feared that they might be worshiped as idols. His policies led to much political and religious discontent, which helped weaken the empire. The empire declined rapidly after Aurangzeb's death on March 3, 1707.

Aurangzeb was born on Nov. 3, 1618, in Dohad, near Ahmadabad. In a struggle for the throne, he defeated three of his brothers in battle and executed two of them. Aurangzeb imprisoned his father and became emperor. Patricia Risso

Aurelian, *aw REE lee uhn* (A.D. 215?-275), was a Roman emperor. His vigorous military rule reunited the empire, which seemed to be breaking up when he came to power. Aurelian stamped his coins with the words *Restorer of the World.* He won victories over barbarian invaders near the Danube River; over Zenobia, queen of Palmyra in Syria; and over Tetricus, a semi-independent ruler of Gaul (now mainly France). Aurelian was born Lucius Domitius Aurelianus, probably in Illyricum, a Roman province on the northeastern coast of the Adriatic Sea. He became emperor in 270 and ruled until 275, when a group of officers murdered him. Most of the wall he started to build around Rome still stands. F. G. B. Millar

Aurelius, Marcus. See Marcus Aurelius.

Auriga, *aw RY guh,* also called the Wagoner or Charioteer, is a constellation between the constellations Perseus and Gemini. Capella is the brightest star in Auriga. In mythology, the Charioteer often represents Phaëthon, son of Helios (see Phaëthon). Sumner Starrfield

Aurochs, *AWR ahks,* also called *urus,* is the name of a kind of extinct wild ox. Aurochs are the ancestors of present-day *domestic* (tame) cattle. After the most recent ice age, which ended about 11,500 years ago, aurochs were spread across Europe, Asia, and northern Africa. Cattle were domesticated by about 8,500 years ago, probably in northern Europe or in India and the Middle East. It is believed they arose from two types of aurochs, one with humps and one without. Aurochs populations were gradually reduced as people hunted them and civilization destroyed their habitats. The last aurochs died in a game preserve in Poland in 1627. William L. Franklin

Scientific classification. Aurochs belonged to the bovid family, Bovidae. Their scientific name is *Bos taurus.*

Aurora, *aw RAWR uh,* was the Roman name for Eos, the Greek goddess of the dawn. She was the sister of Helius, the sun, and Selene, the moon.

Aurora abducted several lovers. The most famous was Tithonus, a brother of King Priam of Troy. Aurora and Tithonus had a son named Memnon, who was killed by the Greek hero Achilles during the Trojan War. Aurora prayed to Jupiter, the king of the gods in Roman mythology, to make Tithonus immortal. However, she forgot to ask for eternal youth for him as well. As a result, Tithonus, though immortal, grew older and older and shriveled up. Aurora had him locked up. He slowly became only a voice. According to one story, Tithonus turned into a grasshopper. F. Carter Philips

Detail of the Aurora Crater (300's B.C.), a vase painting by an unknown Greek artist; Villa Giulio, Rome (SCALA/Art Resource)

Aurora was the Roman name for Eos, the Greek goddess of the dawn. The goddess often carried off handsome men to be her lovers, including the prince Cephalus, *shown here.*

Aurora is a natural display of light in the sky that can be seen with the unaided eye only at night. An auroral display in the Northern Hemisphere is called the *aurora borealis,* or the *northern lights.* A similar phenomenon in the Southern Hemisphere is called the *aurora australis.* Auroras are the most visible effect of the sun's activity on Earth's atmosphere.

Most auroras occur in far northern and southern regions. They appear chiefly as arcs, clouds, and streaks. Some move, brighten, or flicker suddenly. The most common color in an aurora is green. But displays that occur extremely high in the sky may be red or purple. Most auroras occur about 60 to 620 miles (97 to 1,000 kilometers) above Earth. Some extend lengthwise across the sky for thousands of miles or kilometers.

Auroral displays are associated with the *solar wind,* a continuous flow of electrically charged particles from the sun. When these particles reach Earth's magnetic field, some get trapped. Many of these particles travel toward Earth's magnetic poles. When the particles strike atoms and molecules in the atmosphere, energy is released. Some of this energy appears as auroras.

Hopkins Observatory, Williams College (Kevin Reardon)

An aurora glows in the night sky. Most auroras occur in the far northern and far southern regions. But occasionally, strong auroras like this one appear at lower latitudes.

Auroras occur most frequently during the most intense phase of the 11-year *sunspot cycle.* During this phase, dark patches on the sun's surface, called *sunspots,* increase in number. Violent eruptions on the sun's surface, known as *solar flares,* are associated with sunspots. Electrons and protons released by solar flares add to the number of solar particles that interact with the earth's atmosphere. This increased interaction produces extremely bright auroras. It also results in sharp variations in the earth's magnetic field called *magnetic storms.* During these storms, auroras may shift from the polar regions toward the equator. C. R. O'Dell

Auschwitz, *OWSH vihts,* was a forced-labor and extermination center run by the German Nazis during World War II (1939-1945). About $1\frac{1}{4}$ million people died at Auschwitz from September 1941 to January 1945. The Nazis used gas chambers and other methods to murder most of these people. Other victims died of starvation or disease, and some were worked to death in nearby factories. Most of the victims at Auschwitz were Jewish. The Nazis killed them as part of a plan to murder all the Jews in Europe.

Auschwitz was located in Poland, near what is now Oświęcim. It consisted of three concentration camps—Auschwitz I, built in 1940; Auschwitz II, or Birkenau, built in 1941; and Auschwitz III, or Monowitz, built in 1942. Today, Auschwitz is a museum and archive that is preserved by the Polish government. Charles W. Sydnor, Jr.

See also Concentration camp; Holocaust (The camps).

Austen, Jane (1775-1817), one of the best-loved English novelists, wrote with a keen sense of irony about the social institutions of her time. In each of Austen's six novels, a woman meets and marries an eligible man after a series of usually comic difficulties. Overcoming these obstacles helps one or both of the characters gain the self-knowledge required for a happy marriage. Few authors have matched Austen's sure eye for human weakness, her affectionate description of everyday life, or her witty and elegant prose.

Austen's first novel, *Sense and Sensibility* (1811), follows Elinor and Marianne Dashwood, two sisters with differing temperaments. Elinor possesses careful self-control, or "sense," while Marianne permits hasty emotions, or "sensibility," to rule her decisions. *Pride and Prejudice* (1813) is Austen's most famous work. In the novel, the lively Elizabeth Bennet dislikes Fitzwilliam Darcy's proud behavior and is blinded to his better qualities. Their marriage can take place only after he humbles his pride and she loses her prejudice. In *Mansfield Park* (1814), the long-suffering and modest Fanny Price grows up mistreated by rich relatives. Her character may seem uninteresting compared with Austen's more flawed women, but Fanny is a successful portrait of personal integrity.

The self-satisfied and overly imaginative heroine of *Emma* (1816) almost ruins her chances for happiness with matchmaking schemes. *Northanger Abbey,* begun in 1797 and published in 1818, makes fun of the Gothic tales of romance and terror popular in Austen's time (see Gothic novel). In *Persuasion* (1818), Anne Elliot and Frederick Wentworth find love that survives an earlier parting and a disapproving family.

Jane Austen was born on Dec. 16, 1775, in Steventon, a village in Hampshire. Her father was a clergyman, and she received a better education than most women of her time. Austen began writing novels in her early 20's but did not publish them until late in life. Austen never married, and she lived happily in the rural, upper middle class society described in her books. K. K. Collins

Austerlitz, *AW stuhr lihts,* **Battle of,** was a major battle of the Napoleonic Wars. It was fought on Dec. 2, 1805, near the Moravian town of Austerlitz (now in the Czech Republic). Napoleon I and his Grand Army, in his most brilliantly fought battle, defeated a larger, combined army of Austria and Russia. The Battle of Austerlitz led to the Treaty of Pressburg, by which Austria lost Istria and Dalmatia to Italy, and the Tyrol to Bavaria. The Holy Roman Empire, headed by Francis II, was dissolved, and the way opened for Napoleon to rule central Europe. See Napoleon I (Dominates Europe).

Eric A. Arnold, Jr.

Austin (pop. 656,562; met. area pop. 1,249,763) is the capital of Texas and its educational center. The city of Austin lies on the Colorado River, about 160 miles (257 kilometers) west of Houston (see Texas [political map]).

Austin was founded in 1839 and became the capital of the Republic of Texas in 1840. Officials of the republic chose the site, on bluffs overlooking the Colorado River, for its beauty and central location. The city was named for Stephen F. Austin, often called the father of Texas.

Description. Austin, the county seat of Travis County, covers 254 square miles (658 square kilometers). The Austin-San Marcos metropolitan area, which consists of Bastrop, Caldwell, Hays, Travis, and Williamson counties, occupies about 4,282 square miles (11,090 square kilometers).

The State Capitol, Austin's chief landmark, is near the center of the city. State government agencies and institutions are throughout the city. The main campus of the

University of Texas lies near the Capitol. Many athletic and entertainment events take place at the university's Frank C. Erwin Center, with 18,000 seats. Other institutions of higher learning include Austin Community College, Austin Presbyterian Theological Seminary, Episcopal Theological Seminary of the Southwest, Huston-Tillotson College, and St. Edward's University.

The Lyndon Baines Johnson Library on the University of Texas campus houses documents and souvenirs of the 36th President. The Texas Memorial Museum, also on campus, has exhibits on Texas history. The Laguna Gloria Art Museum shows work by Texas artists. Austin has a ballet association and symphony orchestra.

Since 1895, Austin has produced its own "moonlight." Mercury vapor lamps, atop iron frames 165 feet (50 meters) high, cast a blue glow over the city.

Economy. The state, local, and federal governments employ more than a third of Austin's work force. The University of Texas, a state institution, ranks as the largest single employer.

Austin is the market center of a region that raises beef cattle and other farm products. Over 200 trade organizations and associations have headquarters in Austin. The city is a center of the country music industry. Austin is famous for its parks, many of which are linked by *greenbelts* (belts of woodland or parkland).

The Austin metropolitan area has about 550 manufacturing plants. The area is an important center for electronics and other high-technology industry. Many plants work with research institutions based in Austin. Other major industries include publishing and tourism.

Government and history. Austin has a council-manager form of government. The voters elect a mayor and six council members to two-year terms. The council hires a city manager to carry out its policies.

When white settlers first arrived in the early 1800's, Tonkawa Indians lived in what is now the Austin area. The settlers named their community Waterloo. Few families lived there when Austin was founded in 1839.

In 1900, when Austin had 22,258 people, the Colorado River flooded the lower part of the city and burst a dam. Since then, seven new dams have been built. They have created seven artificial lakes near Austin. These lakes provide recreation facilities.

Austin's population has increased by more than a third every 10 years from 1920—when 34,876 people lived in the city—to 2000. During the 1970's, the increases resulted mainly from the growth of the University of Texas and from Austin's development as a center of business and government. During the 1970's and early 1980's, many large construction projects were undertaken in the Austin area. These included many office buildings, apartments, hotels, shopping centers, and university and state government buildings. In 1992, a new convention center opened in Austin. By 2000, Austin's population had reached 656,562. Terry G. Jordan

See also **Texas** (pictures).

Austin, Stephen Fuller (1793-1836), was an American colonizer and pioneer. He started the first American colony in Texas, which was then part of Mexico. His father, Moses Austin, had obtained a grant of land on the Brazos River from Spanish authorities in Mexico in 1821. Moses planned to bring 300 families to settle the land. But he died before establishing the colony. Stephen obtained permission to continue the project—first from Spain, and later from Mexico after it won independence from Spain in 1821. The main settlement was named San Felipe de Austin in Stephen's honor. Later, Austin, Texas, was named for him.

Austin managed the affairs of the colony wisely. By 1830, there were more than 20,000 Americans in Texas. That year, the Mexican government prohibited further immigration of Americans to Texas. This action increased the desire of many Texans for a more independent government. In 1833, when Austin asked Mexico for a separate state government for Texas, he was accused of trying to annex Texas to the United States. He was sent to prison, but never received a trial. He returned to Texas in 1835. There he found the people ready to fight for freedom from Mexico. Austin took command of the Texan army, but soon resigned. He went to the United States for money and supplies for the Texans.

Texas became a republic in 1836. Austin was a candidate for President, but Sam Houston was elected. Austin was named secretary of state. He worked secretly for the U.S. annexation of Texas but died before it happened. He was born in Wythe County, Virginia. A statue of Austin is in the U.S. Capitol. Joseph A. Stout, Jr.

The vast interior of Australia, often called the *outback,* consists mainly of deserts and dry grasslands. Spinifex grass, *foreground,* is a common plant in the outback.

Australia

Australia is the only country that is also a continent. In area, Australia ranks as the sixth largest country and smallest continent. It lies between the South Pacific Ocean and the Indian Ocean, about 7,000 miles (11,000 kilometers) southwest of North America and about 2,000 miles (3,200 kilometers) southeast of mainland Asia. Australia is often referred to as being "down under" because it lies entirely within the Southern Hemisphere. The name *Australia* comes from the Latin word *australis,* which means *southern.* The official name of the country is the *Commonwealth of Australia.*

Much of Australia is dry and thinly populated. However, Australia has numerous areas with a pleasant climate and enough rainfall to support a large population. The southeastern coastal region has the most people by far. Australia's two largest cities—Sydney and Melbourne—lie in this region. Canberra, the national capital, lies only a short distance inland. The huge interior of Australia is mostly desert or dry grassland and has few settlements. The country as a whole averages only about 6 people per square mile (2 people per square kilometer). Most Australians live in urban or suburban areas in the major cities. Australia is famous for its vast open spaces, bright sunshine, and unusual wildlife. Kangaroos, koalas, platypuses, and wombats are only a few of the many unusual animals that live in Australia.

The country was once a group of British colonies, and most Australian people are of British ancestry. When people moved to Australia from Great Britain (now the United Kingdom), they took many British customs with them. For example, Australians drive on the left side of the road, as do British drivers. However, Australians have developed a way of life all their own. Australia has

The contributors of this article are D. N. Jeans, Associate Professor of Geography at the University of Sydney; and John Rickard, Reader in History at Monash University and author of Australia: A Cultural History.

a warm, sunny climate. People spend much of their free time outdoors. Australians love sports and outdoor living in general. Since the 1950's, immigration from many different countries has made the population more mixed and the way of life more varied. Australia now considers itself a multicultural nation.

Australia is one of the world's developed countries. It has busy cities, modern factories, and productive farms and mines. Australia is the world's leading producer and exporter of wool and *bauxite* (the ore from which aluminum is made). The country also produces and exports large amounts of other minerals and farm goods. Income from these exports enables most Australians to have a high standard of living. In the past, the United Kingdom was Australia's leading trading partner. Today, Australia trades most with Japan and the United States.

The first Australians were a people known today as *Aborigines* (pronounced *AB uh RIHJ uh neez*). The Aborigines had lived in Australia for as long as 65,000 years before the first white settlers arrived.

Great Britain settled Australia as a prison colony in 1788. After British settlement, the number of whites steadily increased while the Aboriginal population declined dramatically. The Aboriginal population slowed its decline in the early 1900's and has been increasing since the mid-1900's. Today, the majority of Australians are white or have mixed European ancestry, though there are now also many Australians of Asian and Middle Eastern descent.

Government

The Commonwealth of Australia is a federation of states governed under a written constitution. The Australian Constitution gives certain powers to the federal government and leaves all other powers to the states.

Australia has six states, each with its own government. These states are New South Wales, Queensland, South Australia, Tasmania, Victoria, and Western Australia. Australia also has two mainland territories—the Australian Capital Territory and the Northern Territory. Each territory is responsible for its own administration, the first step toward statehood. But the federal government must approve major policy changes for the territories.

Australia has a *parliamentary* system of government. Under this system, the national government is controlled by the political party or the *coalition* (combination) of parties with a majority of seats in the lower house of parliament. The leader of the majority party or the coalition heads the government as prime minister.

Australia is a constitutional monarchy like the United Kingdom. The British monarch, Queen Elizabeth II, is also queen of Australia and the country's head of state. However, the queen has little power in Australia. She serves mainly as a symbol of the historical tie between the two countries. Australia is a member of the Commonwealth of Nations, an association formed by the United Kingdom and some former British colonies.

The federal government of Australia is officially headed by a *governor general,* who represents the queen. The queen appoints the governor general on the recommendation of the Australian prime minister. The governor general's role, like the queen's, is mainly symbolic. In 1975, however, the governor general used his power to remove the prime minister from office. See the *History* section of this article for details.

The prime minister, Australia's head of government, is normally responsible only to the majority party or coalition. If the party or coalition chooses a new leader, that person becomes prime minister.

The prime minister appoints members of Parliament to head government departments. The department heads, called *ministers,* and the prime minister make up the Cabinet, which sets major government policies.

The federal Parliament has an upper and a lower house. The upper house is called the Senate, and the lower house is called the House of Representatives.

John Carnemolla, Australian Picture Library

Sydney is the largest city in Australia. Founded in 1788, it is also the country's oldest city. Today, the downtown area of Sydney has many high-rise buildings. The sail-like Sydney Opera House, *foreground,* stands on a peninsula in Sydney Harbour and is a city landmark.

Australia in brief

General information

Capital: Canberra.
Official language: English.
Official name: Commonwealth of Australia.
Anthems: "Advance Australia Fair" (national); "God Save the Queen" (royal).
Largest cities: (1996 census)
- Sydney (3,741,290)
- Melbourne (3,138,147)
- Brisbane (1,488,883)
- Perth (1,244,320)
- Adelaide (1,045,854)

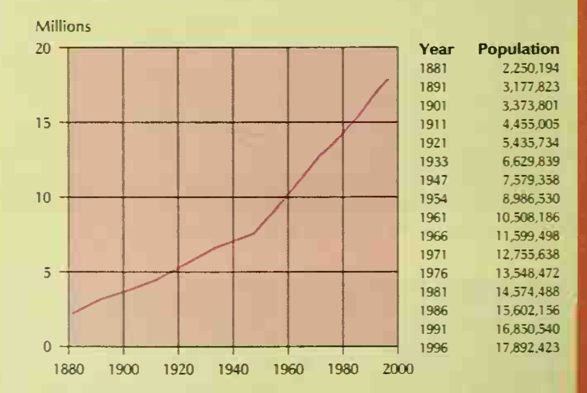
Australia's flag has a British Union flag, five stars that represent the constellation Southern Cross, and a large star for the country's states and territories.

Australia's coat of arms features a kangaroo and an emu; golden wattle blossoms (the national floral emblem); a shield with the coats of arms of the six states of Australia; and a star for the states and territories.

Land and climate

Land: Australia is the only country that is also a continent. It lies between the South Pacific and Indian oceans. Australia is mostly flat, except for the Great Dividing Range in the east and several smaller mountainous regions. The major rivers include the Murray and the Darling.

Area: 2,978,147 mi^2 (7,713,364 km^2), including 26,000 mi^2 (67,800 km^2) for Tasmania. *Greatest distances* (mainland)—east-west 2,475 mi (3,983 km); north-south—1,950 mi (3,138 km). *Coastline*—37,118 mi (59,736 km), including 1,760 mi (2,833 km) for Tasmania and 14,825 mi (23,859 km) for offshore islands.
Elevation: *Highest*—Mt. Kosciuszko, 7,310 ft (2,228 m) above sea level. *Lowest*—Lake Eyre, 52 ft (16 m) below sea level.
Climate: The northern third of Australia lies in the tropics and is warm the year around. The rest of the country has warm summers and cool winters. About a third of the country is desert. Australia lies south of the equator, and so its seasons are opposite those in the Northern Hemisphere.



Government

Form of government: Constitutional monarchy; in practice, a parliamentary democracy.
Head of state: Queen of the United Kingdom, who is also queen of Australia. In practice, governor general performs functions in queen's absence.
Head of government: Prime minister, the leader of the party or coalition of parties holding a majority in the House of Representatives.
Parliament: *Senate*—76 members; *House of Representatives*—150 members.
Executive: Prime minister and Cabinet.
Political subdivisions: Six states, two mainland territories, and eight external territories.

People

Population: *2002 estimate*—19,231,000. *1996 census*—17,892,423.
Population density: 6 per mi^2 (2 per km^2).
Distribution: 85 percent urban, 15 percent rural.
Major ethnic/national groups: About 91 percent of European descent, chiefly British and Irish, but also Italian, Greek, German, Dutch, and others. About 7 percent Asian. About 2 percent Aborigine (native Australian peoples).
Religion: About 25 percent Anglican, 25 percent Roman Catholic, and 10 percent *Uniting Church,* which consists of Methodist, Congregationalist, and some Presbyterian churches.

Population trend

Year	Population
1881	2,250,194
1891	3,177,823
1901	3,373,801
1911	4,455,005
1921	5,435,734
1933	6,629,839
1947	7,579,358
1954	8,986,530
1961	10,508,186
1966	11,599,498
1971	12,755,638
1976	13,548,472
1981	14,574,488
1986	15,602,156
1991	16,850,540
1996	17,892,423

Economy

Chief products: *Agriculture*—apples, barley, beef cattle, chickens and eggs, grapes, milk, oats, oranges, potatoes, rice, sheep and lambs, sugar cane, wheat, wool. *Fishing*—lobsters, oysters, shrimp. *Forestry*—eucalyptus and pine timber, wood pulp. *Manufacturing*—automobiles and other transportation equipment; chemicals; household appliances; iron, steel, and other metals; paper; processed foods; textiles, clothing, and shoes. *Mining*—bauxite, coal, copper, diamonds, gold, iron ore, lead, manganese, natural gas, nickel, opals, petroleum, silver, tin, titanium, uranium, zinc, zircon.
Money: *Basic unit*—Australian dollar.
International trade: *Major exports*—alumina, beef, coal, iron ore, petroleum products, wheat, wool. *Major imports*—electrical appliances, industrial machinery, office equipment, petroleum products, telecommunications equipment, yarns and fabrics. *Major trading partners*—Germany, Japan, New Zealand, United Kingdom, United States.

Most bills are introduced in the House. The Senate reviews bills passed by the House and can reject them.

The Australian Senate has 76 members. Each state elects 12 senators, and each mainland territory elects 2. Membership in the 150-member House of Representatives is divided among the states and mainland territories according to population. Senators are elected to six-year terms, and representatives to three-year terms. Elections for the House must be held at least every three years. But the prime minister may ask the governor general to dissolve the House and call for new elections at any time. All Australians 18 years of age or older must vote in parliamentary and state elections. Those who do not vote may be fined.

The federal courts. The High Court of Australia decides constitutional questions. It also serves as the nation's court of final appeals. Other federal courts deal with bankruptcy cases, family law, industrial disputes, and violations of federal law.

State and local government. Each Australian state has its own parliament, court system, head of government, and governor. The heads of state governments are

National Capitol Development Commission

Parliament House in Canberra is the meeting place of the Australian Parliament. The unusual structure is set into a hill overlooking the city. The building was dedicated in 1988.

called *premiers.* The governor of each state represents the queen.

Australia's states do not operate as independently of the federal government as do, for example, the states of the United States. The Australian states have heavy administrative responsibilities in certain areas, such as local law enforcement, public education, and the building of roads. But the federal government collects nearly all the nation's taxes. Each state receives a share of the federal tax income. But this allowance is usually not enough to finance major new public works. By granting or denying a state's requests for additional funds or loans, the federal government strongly influences the services that the state provides.

Local governments in Australia consist mainly of *shire* (county) and city or town councils. Local governments are responsible for such services as building local roads, maintaining public libraries, and collecting the residents' garbage. The states, rather than local governments, control the local public schools and police. Local governments receive income from property taxes and federal and state grants.

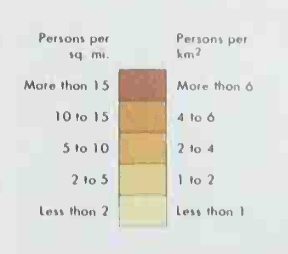
Political parties. Australia has three main political parties—the Australian Labor Party (ALP), the Liberal Party of Australia, and the National Party of Australia. The ALP promotes government action in economic and social affairs, especially to improve working conditions. Many ALP supporters belong to labor unions. The Liberal Party favors the free enterprise system with little government interference. Many merchants and business executives support the Liberals. The National Party represents the interests of farmers and other rural Australians. In Parliament, the Liberal and National parties often form a coalition in opposition to the ALP.

Environmental issues are becoming increasingly important to Australians. Today, the parties' positions on such issues strongly influence voters.

The armed forces of Australia consist of the Australian Army, the Royal Australian Navy, and the Royal Australian Air Force. The three services make up a united command that is called the Australian Defence Force. The Australian Defence Force has a total of approximately 70,000 men and women. All of the military service is voluntary.

People

Population and ancestry. Approximately 80 percent of Australia's people live in the southeastern quarter of the country, especially in large cities along the coast. Most of the rest of the people live along the northeast and the extreme southwest coasts. The vast interior of Australia is too dry to support a large population, and few people live there. Canberra, the national capital, is the largest inland city. It lies only about 80 miles (130 kilometers) from the ocean.



Most Australians are European immigrants or descendants of European immigrants. Aborigines make up about 2 percent of the population. Traditionally, Australia has relied heavily on immigrants to build up its labor force. Through the years, millions of immigrants have been attracted to Australia by the promise of high-paying jobs, security, and a clean environment.

Until the mid-1900's, the great majority of Australia's immigrants came from the United Kingdom and Ireland.

Where the people of Australia live

This map shows how Australia's population is distributed. Most of the people live along the east, southeast, and extreme southwest coasts. The vast, dry interior of the country has few settlements.

A street scene in Perth reflects the strongly European ancestry of the Australian people. The great majority of Australians are descendants of British or Irish immigrants.

Bill Bachman

Aborigines are descendants of Australia's first settlers, people who migrated from Asia thousands of years ago. This school for Aboriginal children is in the Northern Territory.

As a result, most Australians are of British or Irish ancestry.

After World War II ended in 1945, the government began a special program to encourage mainland Europeans left homeless by the war to move to Australia. The government later broadened this program to include any Europeans who wished to move to Australia and could meet the country's immigration requirements. In general, the immigration authorities prefer applicants who have some special job skill and a stable personal background.

Australia has an exceptionally large foreign-born population because of the high rate of immigration since World War II. About 22 percent of all Australians were born in other countries. Australia has admitted about 6 million immigrants since the end of World War II. Approximately one-third of these immigrants have come from the United Kingdom and Ireland. The majority of the rest of the immigrants have come from mainland Europe, especially from the former Yugoslav republics and from such southern European countries as Greece and Italy.

Relatively few Canadians and Americans have moved to Australia. Immigration from Asia has greatly increased since the 1970's, and European immigration has declined. During the late 1900's, the number of immigrants from New Zealand and Southeast Asia increased rapidly.

Language. English is the official language of Australians. However, more than 15 percent of the people speak a language other than English at home. The most common languages after English are Chinese, Italian, Greek, Vietnamese, and Arabic.

Australian English differs from British English in certain ways. The British who settled in Australia had to develop a vocabulary to describe the many unfamiliar animals and plants in their new environment. In some cases, the settlers used existing English words. For example, they gave the name *magpie* to a bird that resembles the British magpie but is actually unrelated to any bird in the United Kingdom.

In other cases, many of the British settlers borrowed words from the language of the Aborigines. Such Aboriginal words as *kangaroo* and *koala* were thus introduced into English.

Pioneer settlers in the Australian interior invented a large, colorful vocabulary. Large farms became known as *stations,* farm owners as *squatters,* a herd of animals as a *mob,* and wild horses as *brumbies.* The interior itself became known as the *outback.*

Australian English has also produced many colorful figures of speech. For example, an exceptionally brave person is said to be "as game as Ned Kelly." Ned Kelly was a famous Australian outlaw of the 1870's. "Waltzing Matilda," which is the title of Australia's most famous song, refers neither to a dance nor to a woman. A *matilda* is a blanket roll. "To waltz matilda" means "to tramp the roads."

Australians speak with an accent that differs from the accents in other English-speaking countries around the world. The accent differs little from one part of Australia to another. However, it varies somewhat according

to a person's family background, amount of schooling, and gender.

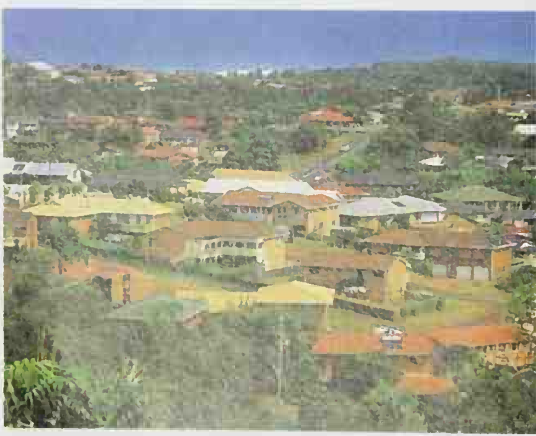
The Aborigines. Australia has about 400,000 Aborigines. Most are of mixed Aboriginal and white ancestry. The rest are of unmixed ancestry. Many Aborigines live in or near cities and towns. Some live in rural areas of New South Wales, the Northern Territory, Queensland, and Western Australia. Torres Strait Islanders make up Australia's other *indigenous* (native) group.

The history of the Aborigines since the arrival of Europeans has been similar to that of the American Indians. Many Aborigines were killed or forced from their homes by white settlers. Since then, most Aborigines have lived on the fringes of white society. In many cases, they have been actively discouraged from joining white communities. The majority of Aborigines live in cities and towns, though many retain strong links with their Aboriginal community and traditional lands. Since the late 1900's, some Aborigines in central and northern Australia have stayed on, or returned to, their traditional lands. There they often live in Aboriginal community settlements. These communities preserve some Aboriginal ways of life, especially traditional languages, religious beliefs, and styles of painting and craftwork.

Regardless of where they live, the Aborigines generally lag far behind white Australians in education and income. They also lack decent housing and proper health care. Some whites have tried to help the Aborigines raise their standard of living. But for many years, churches and other private groups provided the only organized assistance. A clause in the Australian Constitution prevented the federal government from aiding most Aborigines directly. But in 1967, Australians voted overwhelmingly to remove this clause from the Constitution.

Today, the Australian government has programs to improve the health, education, job skills, and living conditions of the Aborigines. The government also has a program to help Aboriginal communities in rural areas gain title to their land. However, many Aborigines want a greater voice in deciding their own affairs. They especially want to regain control over all their traditional tribal territories, not only those lands occupied by Aboriginal communities. For detailed information on the Aborigines, see the article **Aborigines, Australian.**

Ways of life



For most of the 1900's, the difference between rich and poor in Australia was smaller than in most other Western countries. In the late 1900's, this gap began to grow rapidly. Australia now has clear differences in wealth, employment, and education among its people. But except for some Aborigines, Australia still lacks the extremes of poverty found in other developed countries.

Australia does not have strong regional differences in cultures or lifestyles. However, rural lifestyles differ from those in the cities. Many rural regions are poorer than city areas. The rural areas have higher levels of unemployment, reduced access to cultural and educational institutions, and fewer government and commercial services. Rural and urban voting patterns also differ. Rural voters more often support conservative candidates.

City life. More than 80 percent of all Australians live in cities and towns, making Australia one of the world's most urbanized countries. About 70 percent of all Australians live in cities of more than 100,000 people. These cities include the federal capital, Canberra, and the six state capitals. The state capitals are Sydney, New South Wales; Melbourne, Victoria; Brisbane, Queensland; Perth, Western Australia; Adelaide, South Australia; and Hobart, Tasmania. Canberra is smaller than all the state capitals except Hobart. Sydney and Melbourne are by far the biggest cities in Australia. Sydney has about 3 $\frac{3}{4}$ million people, and Melbourne about 3 million.

Each state capital is not only the political center but also the chief commercial, industrial, and cultural center of its state. Each is the oldest or one of the oldest settlements in the state. Each was laid out near the mouth of a river and as close as possible to a good ocean harbor. The river provided drinking water. The harbor enabled the settlement to develop into a center of trade and immigration. These advantages helped each state capital become the largest city in its state.

The main business district of each state capital is its oldest section, the area nearest the waterfront. In the

Housing in Australia varies from city to city. Most families live in single-story dwellings, such as these in Port Macquarie, New South Wales. Each house typically has its own garden.

© Philip Quirk, Wildlight

An Asian food shop operates in Sydney's Chinatown. Most Australians have British or Irish ancestors, but increasing numbers of Asians have settled in the country since the 1970's.

largest cities, most of the original buildings in this section have been replaced by modern structures, including many high-rise office buildings. In addition to office buildings, the downtown areas have fine shops, theaters, and restaurants.

Most urban dwellers in Australia live in suburbs that extend outward from a central business district. The suburbs have their own schools, churches, shopping centers, and recreational facilities. Some suburbs, especially those near Sydney and Melbourne, also have industrial districts. Most families live in single-story houses, each with its own garden. About three-fourths of all families own their own homes. Older styles of housing differ from city to city. In Queensland cities, for example, older houses are made of wood, have *verandas* (wide porches), and are raised above the ground on poles called *stumps*. In Melbourne and Sydney, many older houses are made of brick or stone and stand in rows called *terraces*. Since the late 1900's, developers have built new high-rise apartment buildings in the central areas of large cities. Older buildings, such as factories and warehouses, have been turned into modern apartments.

Australia's big cities have problems common to all big cities, including air pollution and rush-hour traffic jams. Before the 1950's, the inner suburbs, those closest to the city, were the poorest residential areas. These areas had high rates of unemployment and crime. But in the 1950's, many non-British immigrants began settling in the inner-city suburbs and helped regenerate them. Many middle-class residents have moved to these areas. Many poorer families now live in the outer suburbs.

Country life. Only about 15 percent of Australia's people live in rural areas. Australians call the remote countryside the *bush*. The term *outback* refers to the interior. The outback consists mainly of open countryside, including vast grazing lands. It also has widely scattered settlements. The largest ones are mining towns.

Nearly all farms in the outback are cattle, sheep, or wheat *stations* (farms). Life on the stations tends to be extremely isolated. The largest stations cover over 1,000 square miles (2,600 square kilometers) and so may be 100 miles (160 kilometers) or more from the nearest town. In addition, the outback has few paved roads, and so travel by automobile may be difficult or impossible. Many well-to-do farm families have a light airplane for transportation to and from town. Families who do not own a plane may get to town only a few times a year. In farming regions nearer the coasts, the towns are larger and closer together. But even in those regions, farm families may feel far removed from the life of the cities.

All rural areas in Australia are subject to such disasters as droughts, floods, and bushfires. Because they share the threat of frequent disaster, rural Australians tend to feel exceptionally strong ties with one another. Their sense of community is reflected in the fact that they have long had their own political party, the National Party. Many rural communities in Australia have their own traditional fairs, festivals, and sports competitions.

Poverty is a problem in some rural areas due to the lack of local employment. However, most farm families own their farms and live comfortably. Older farmhouses are built of wood and surrounded by a veranda. Newer

© Robert Frerck

Sheep auctions, such as this one in New South Wales, are a familiar sight in rural Australia. The raising of sheep for both wool and meat is one of the country's chief economic activities.

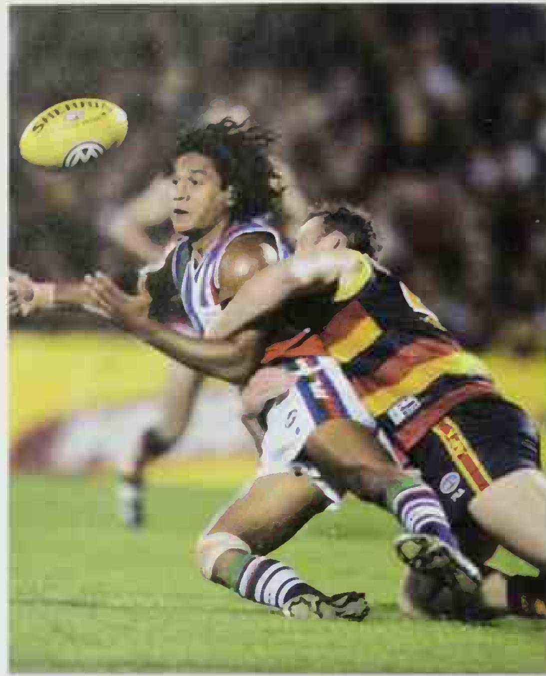
John Baker, Australian Picture Library

Rural communities in Australia serve mainly as marketing and shopping centers for farmers. This community, Tanunda, lies in a grape-growing and winemaking region northeast of Adelaide in South Australia.

farmhouses are constructed of bricks. Nearly all the houses have electric power, and a growing number of them have air conditioning.

Food and drink. Meat is plentiful in Australia and makes up a large part of the people's diet. Beef is the most popular meat, followed by poultry, pork, and lamb and mutton. British customs strongly influenced Australian food choices until after World War II ended in 1945. Since the late 1900's, the number of immigrants from mainland Europe has increased, and more Australians travel to Europe and other areas. As a result, Italian, Greek, and other European styles of cooking have become popular. In restaurants and homes, Australian food also shows the strong influence of Indian and Southeast Asian cooking styles. Chinese restaurants are common throughout Australia. In addition, larger cities have Indian, Japanese, Thai, and Vietnamese restaurants.

Tea is the favorite hot drink of many older Australians. Most younger Australians prefer coffee. Coffee consumption has about quadrupled since the mid-1900's, while tea consumption has declined. Beer is the most popular alcoholic drink. Wine consumption has increased since the 1980's. Australia is an important wine producer, and many Australians drink wine regularly.



Recreation. Most Australians enjoy such recreation as visiting with friends, going for a drive or walk, or watching television. Outdoor sports are extremely popular. Many people enjoy skin diving, surfing, swimming, or boating. Many also play golf and tennis. Team sports are a national pastime. Australians begin to play team sports in elementary school, and many continue to play them throughout life. The best players may work their way up through local and state competitions and perhaps win a position on one of the national teams. The nation's professional sports teams have large and enthusiastic followings.

The most popular team sports in Australia are cricket, Australian rules football, rugby league, rugby union, basketball, soccer, and netball. Cricket, an English game played with bats and ball, is a favorite summer sport in Australia. The Australian national cricket team regularly plays against teams from England, India, New Zealand, Pakistan, South Africa, and the West Indies.

Australian rules football, rugby league, rugby union, and soccer are played mainly during the winter. Australian rules football was invented in Australia and is played mainly there and in the former Australian possession of Papua New Guinea. It is especially popular in southern Australia. Rugby league and rugby union are forms of football invented in England. Rugby league is the professional form of the sport, and rugby union is the amateur form. Australia plays rugby league and rugby union chiefly against France, New Zealand, and the United Kingdom. Soccer is the fastest-growing team sport in Australia. The national soccer team plays teams from many other countries. Netball is a goal-scoring game of throwing and catching that is played by two teams.

Australia has produced many world-famous athletes, especially in tennis, golf, swimming, and track and field. Top Australian tennis stars include Evonne Goolagong Cawley, Margaret Smith Court, Lleyton Hewitt, Lew Hoad, Rod Laver, John Newcombe, Patrick Rafter, and Ken Rosewall. Bruce Crampton, Kel Nagle, Greg Norman, Peter Thomson, and Karrie Webb have been among Australia's top golfers. Well-known Australian swimmers include Rebecca Brown, Dawn Fraser, Shane Gould, Grant Hackett, Susie O'Neill, Kieren Perkins, Samantha Riley, Murray Rose, Ian Thorpe, and Tracey Wickham. Famous Australian track and field stars include Ron Clarke, Herb Elliott, Cathy Freeman, and John Landy. Australians have won numerous Olympic medals in swimming, track and field, rowing, cycling, and yachting. Australians also compete successfully in the international sport of surfing.

Some of Australia's sporting events receive world-

Cricket, an English game played with bats and a ball, is a favorite summer sport in Australia. Teams from each Australian state play each year in a championship series.

Photographic Library of Australia

Surfboat races, such as this one at a beach in Sydney, are a favorite sport in the coastal cities. A race begins with each team rowing out from the shores. The teams then round a marker and race one another back to shore on the surf.

wide attention. Probably the most famous event is the annual Melbourne Cup, a horse race attended by racing fans from throughout the world.

Education. Each Australian state and mainland territory has its own laws concerning education. The federal government regulates education in the other territories. In all the states and territories except Tasmania, children must attend school from age 6 to age 15. However, they may start school before the age of 6, and most start at age 5. Tasmania requires children to attend school from age 6 to age 16. About 70 percent of Australian students attend government schools. The rest attend Roman Catholic or other private schools.

Each Australian state operates its own public school system. But the state systems depend on the federal government for most of their funds. The Roman Catholic Church owns and operates most of Australia's private schools. Unlike the public schools, most of the private schools in Australia charge a tuition fee. The federal government grants funds to assist the private schools.

Australian elementary schools provide six to eight years of study. The number of years varies from one state or territory to another and in some cases includes a year of kindergarten. Australian secondary schools offer five or six years of education, depending on the system of the state or territory. About four-fifths of the students continue beyond the required years of schooling, and about three-fourths of the students graduate from secondary school. Most of the students who graduate from secondary school go on to a university or college.

Many Australian children in remote areas are educated at home by means of traveling teachers and correspondence schools, often called *schools of the air.* Each state operates a correspondence school for children in isolated areas. The Northern Territory operates two such schools. The students receive and turn in their assignments by mail. Four states and the Northern Territory operate schools of the air to enable students to communicate with teachers directly. The teachers are stationed at broadcasting centers in various parts of the country and communicate with students by means of two-way radios, computers, televisions, and fax machines.

Australia has about 40 universities and colleges. Most of Australia's universities are publicly owned. Each university offers undergraduate and graduate studies. Australia also has several publicly owned colleges of advanced education that offer various degrees. Students at publicly owned universities and colleges pay tuition that covers part of the cost of their education, and the federal government pays the rest. Tuition costs at Australia's private universities are considerably higher.

Australia has many public and school libraries. For information about Australia's libraries, see **Library** (Australia and the Far East).

Religion. The Australian Constitution forbids a state religion and guarantees religious freedom. The great majority of Australians are Christians, but many do not attend church regularly. The Anglican Church and the Roman Catholic Church have the most members.

Smaller numbers of Australians belong to the Baptist, Eastern Orthodox, Lutheran, and *Uniting* churches. The Methodist Church of Australia joined with a majority of the country's Congregationalists and Presbyterians to form the Uniting Church in 1977. Australia still has some

© Australian Picture Library

Schools of the air help children in remote areas of Australia obtain an education at home. Teachers communicate with students using two-way radios, computers, and other equipment.

Congregational and Presbyterian churches. But the total membership of these churches is relatively small. The Uniting Church is now Australia's third largest religious denomination. Australia has small Jewish and Muslim minorities. About one-fourth of the population claim no specific religion.

The religions growing most rapidly in Australia are Buddhism, Hinduism, and Islam. The proportion of Christians is declining. In general, the size of Australia's religious groups reflects the ancestry of the people. For example, the Anglican Church began in England, the source of many Australian immigrants. The large number of Roman Catholics reflects the fact that many of the immigrants came to Australia from Ireland, Italy, and other Catholic countries. Muslims or their ancestors migrated chiefly from the Middle East and from southern and southeastern Asia. Most of Australia's Jews, or their parents or grandparents, came from mainland Europe.

The arts

The federal government helps fund the major opera, ballet, and theater companies; the major symphony orchestras; and the motion-picture industry. It gives financial help to writers, painters, musicians, and composers.

Literature. Until the late 1900's, few Australian literary works written before the 1890's were read. The exceptions included two novels—one by Marcus Clarke and the other by Thomas Alexander Browne, writing under the name Rolf Boldrewood. Clarke's novel, *His Natural Life* (1874), tells about life in an Australian prison colony. Browne's classic novel, *Robbery Under Arms* (1888), is an adventure tale about a gang of Australian *bushrangers* (outlaws). A number of early colonial writers, including novelists Ada Cambridge and Tasma (Jessie Couvreur), have been rediscovered.

During the 1890's, Australian writers began to create a national literature. Poems known as *bush ballads* became popular. They describe the colorful, adventurous life in the Australian countryside from the 1860's to the 1890's. Andrew Barton (Banjo) Paterson was the leading bush ballad poet. His most famous work is "Waltzing Matilda." Many critics regard Henry Lawson as the finest Australian writer of the 1890's. He is best known for his short stories and poems about life in the bush.

Many Australian writers of the 1900's wrote about life in the city as well as the bush. The novelist Patrick White belonged to this tradition. White won the 1973 Nobel Prize in literature. His best-known novels include *The Tree of Man* (1955), *Voss* (1957), and *Riders in the Chariot* (1961). Thomas Keneally's works explore the topics of goodness, guilt, and sin. His most famous novels include *Bring Larks and Heroes* (1967) and *Schindler's Ark* (1982; U.S. title *Schindler's List*). Arthur Upfield's works include detective stories whose hero is a part-Aborigine detective and tracker named Napoleon Bonaparte. Other well-known writers include Peter Carey, Shirley Hazzard, Henry Handel Richardson, Christina Stead, and Randolph Stow.

Painting. The Aborigines had a highly developed artistic tradition long before the first European settlers arrived in Australia. They painted on bark and rock and made elaborate designs of human and animal figures. Albert Namatjira, an Aborigine, adopted some European techniques and painted scenes of the Australian desert.

The first major white Australian painters worked during the late 1800's. These painters were influenced by the French impressionists, who tried to catch the ever-changing effects of nature in their works. They often worked in Heidelberg, near Melbourne, and became known as the Heidelberg School. Leaders of this school included Charles Conder, Frederick McCubbin, Tom Roberts, and Arthur Streeton.

During the 1900's, a number of Australian painters developed highly individual styles. The portrait painter

Australian National Gallery

Painting in Australia has a long history. Long before the Europeans arrived, the Aborigines painted elaborate designs of human and animal figures on bark or rock. The bark painting at the left, by a present-day Aboriginal artist, is in the traditional style. Australian artworks from the 1900's are among the works in the Australian National Gallery in Canberra, *shown here.*

Symphony concerts are presented regularly in all of Australia's large cities. This performance is being given in the main concert hall of the Sydney Opera House.

William Dobell became famous for his revealing character studies. Russell Drysdale became known for his haunting pictures of the outback. Sidney Nolan created fantastic, dreamlike paintings based on themes from Australian folklore. During the middle and late 1900's, paintings of the outback by Frederick Williams won much admiration. Today, there is great interest in Aboriginal art.

The Australian National Gallery in Canberra houses the country's national art collection. The National Gallery of Victoria, in Melbourne, and the Art Gallery of New South Wales, in Sydney, also have major collections.

Music and dance. Australia has a national opera company, the Australian Opera, and a national ballet company, the Australian Ballet. Such state companies as the Sydney Dance Company and the Victoria State Opera are well known. Each state capital has a professional symphony orchestra. A number of world-famous singers and composers were born in Australia. They include opera singers Marjorie Lawrence, Dame Nellie Melba, and Dame Joan Sutherland and composers Percy Grainger and Peter Sculthorpe. Modern composer Richard Meale is known for his stage and instrumental works, including the opera *Voss* (1986).

Theater and motion pictures. Each of Australia's state capitals has a permanent company of professional actors and actresses. Each company offers a yearlong season of classical and modern plays.

Australia became one of the first countries to develop a motion-picture industry. Australian filmmakers produced their first feature motion picture in 1906, only three years after the first such film was made in the United States. The Australian film industry practically died out after the late 1930's because of competition from American and British movies. But Australian filmmaking began to revive during the late 1960's. Today, the industry produces 20 or more feature films a year, and a growing number are distributed overseas.

Several famous stage and movie stars were either born or raised in Australia. They include Dame Judith Anderson, Judy Davis, Peter Finch, Errol Flynn, Paul Hogan, and Cyril Ritchard.

Architecture. During the 1800's, many public buildings and private houses in Australia were built in the Georgian or Victorian style of architecture. Both these styles originated in England. The Georgian style featured a simple square or rectangular design and classical ornaments, especially columns. The Australian version of the Georgian style introduced the veranda as a basic element of the country's architecture.

Most Victorian buildings had an irregular shape and elaborate ornaments, such as spires and pointed domes. The railings and roof supports for Victorian verandas were made of showy iron grillwork. There is an active state-supported movement to preserve Australia's historic buildings. Some fine examples of Georgian and Victorian architecture have been preserved. But many

Lightstorm, Australian Picture Library

Modern high-rise buildings tower above older brick buildings in Adelaide, *above*. During the middle and late 1900's, all the major cities of Australia built similar high-rise structures.

The Eastern Highlands extend in a narrow band along Australia's east coast. They are sometimes called the Great Dividing Range because their slopes divide the flow of rivers in the region. The highlands are the most fertile land region in Australia.

have been replaced by modern structures.

Today, Australia's architecture is international in style. All the large cities have towering structures of concrete, steel, and glass. These high-rises differ little from those in other countries. However, some modern Australian architecture is highly unusual. The Sydney Opera House, a spectacular structure with saillike roofs, has attracted worldwide attention since its completion in 1973. It was designed by Danish architect Jørn Utzon.

The land

Australia is surrounded by water, like an island. But geographers class it as a continent rather than as an island because of its great size. It is sometimes referred to as an "island continent."

Australia covers about 5 percent of the earth's land area. The island of Tasmania, which lies about 130 miles (209 kilometers) south of the Australian mainland, is considered part of the continent. Tasmania was part of the mainland until about 12,000 years ago. It became separated because the level of the ocean rose and covered the land connection.

Most of Australia is low and flat. The highest and most mountainous land lies along the east coast. Nearly all the land west of this region—about 90 percent of the total land area—consists of level plains and plateaus.

Land regions. Australia can be divided into three major land regions. They are, from east to west: (1) the Eastern Highlands, (2) the Central Lowlands, and (3) the Western Plateau.

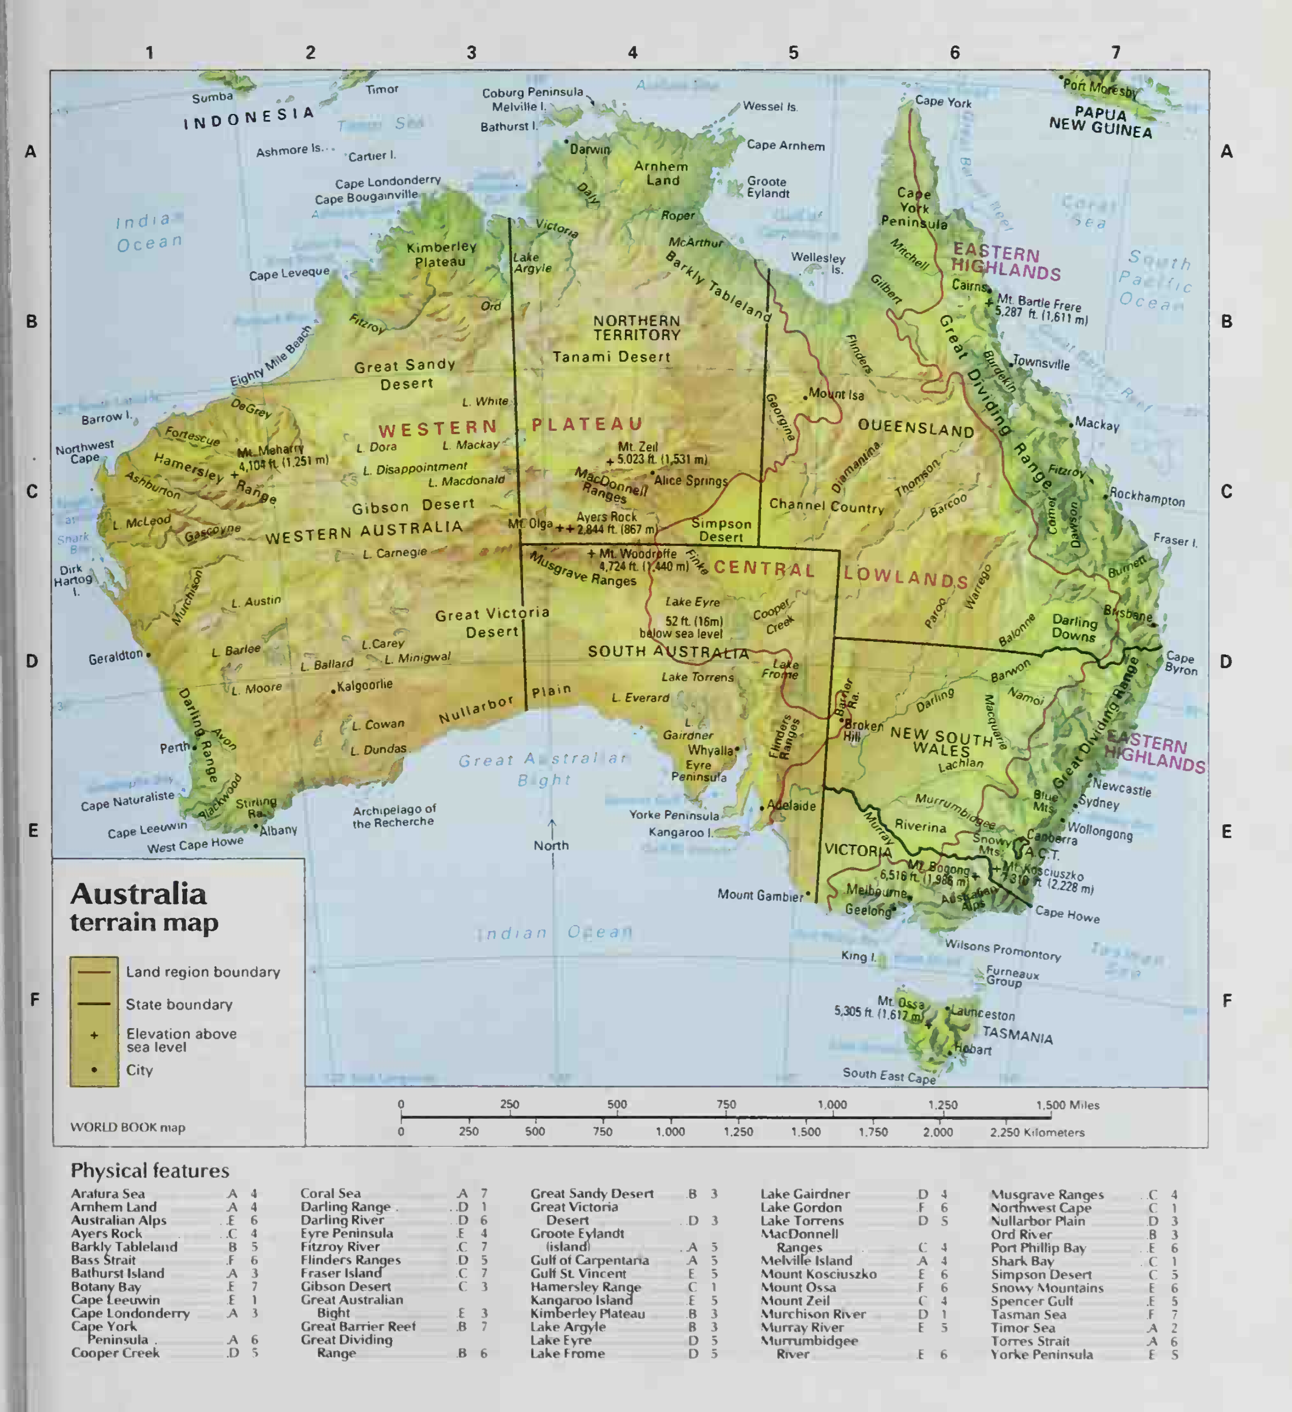
The Eastern Highlands include the highest elevations in Australia. The region extends from Cape York Peninsula in extreme northeastern Australia to the south coast of Tasmania. A low plain bordered by sandy beaches and rocky cliffs stretches along the Pacific coast. More rain falls on this coastal plain than anywhere else in the country. The southeastern section of the plain, from Brisbane to Melbourne, is by far the most heavily populated part of Australia.

The Eastern Highlands are sometimes called the *Great Dividing Range* because their slopes divide the flow of the rivers in the region. Rivers that flow down the eastern slopes empty into the ocean. Rivers that run down the western slopes flow to the Central Lowlands. However, the highlands are not a single range, nor are they especially mountainous. They consist mainly of high plateaus that are broken in many places by gorges, hills, and low mountain ranges.

Many of the plateaus have fertile soils and are used as cropland. Grass or forests cover other plateaus. At one time, forests also covered much of the coastal plain. Except in the far north, however, most of the coastal forests have been cleared for farms and cities.

The Central Lowlands have the lowest elevations in Australia. The region is generally flat. Many rivers flow through the lowlands after heavy rains. Rains are infrequent, however, except along the region's north and south coasts and near the Eastern Highlands. Riverbeds farther inland are dry most of the year.

Farmers in the southern part of the Central Lowlands grow wheat. Most of the rest of the region is too dry or too hot for most kinds of crops. However, much of the land is covered with coarse grass or shrubs and is used to graze livestock. The west-central part of the region is a barren, sandy desert. Lake Eyre, the lowest point in Australia, lies 52 feet (16 meters) below sea level along the southern edge of this desert.



The region has no large cities. The two biggest cities—Mount Isa and Broken Hill—have fewer than 30,000 people each. Both cities are mining centers.

The Western Plateau covers the western two-thirds of Australia. The region has a higher average elevation than the Central Lowlands. However, most of the land is flat, as in the lowlands.

Deserts cover the central part of the Western Plateau. Except in the south and northeast, the deserts gradually give way to land covered by grass and shrubs. Much of this land is used to graze livestock. Low mountain ranges rise above the general level of the plateau in the grazing areas. Rainfall is heaviest in the extreme north and southwest. These areas have most of the region's cropland. A vast, dry, treeless plateau called the Nullarbor Plain extends about 400 miles (640 kilometers) along the southern edge of the region. The name *Nullarbor* comes from the Latin words *nulla* and *arbor,* which mean *no tree.*

The Western Plateau region has two large cities, Adelaide and Perth. Both cities lie on coastal plains, Adelaide in the extreme southeastern part of the region and Perth in the extreme southwest.

Mountains. Australia's highest mountains rise in the Australian Alps in the extreme southern part of the Eastern Highlands. The Australian Alps consist of several ranges. The Snowy Mountains are the best known. Aus-

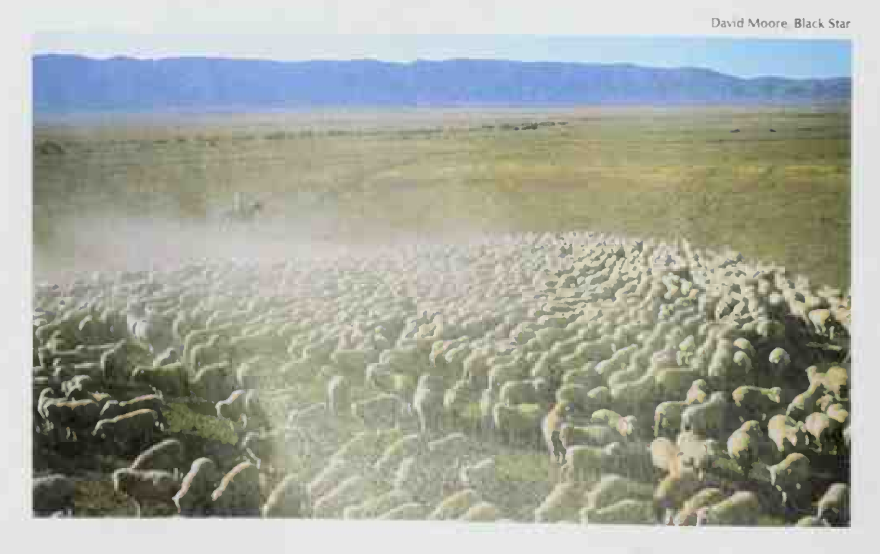
tralia's highest peak, Mount Kosciuszko, rises 7,310 feet (2,228 meters) above sea level in the Snowy Mountains. Mount Kosciuszko and other tall peaks in the Australian Alps are snow covered in winter and attract many skiers.

The mountain ranges in the Western Plateau are much lower than those in the Australian Alps. The highest peaks are in the MacDonnell and Musgrave ranges in central Australia. Ayers Rock, called *Uluru* (great pebble) by the local Aborigines, is a huge loaf-shaped rock formation just south of the MacDonnell Ranges in Uluru-Kata Tjuta National Park. It is a major tourist attraction.

Deserts cover about a third of Australia. The country has four major deserts. The Simpson Desert lies along the western edge of the Central Lowlands. The three other deserts—the Gibson, Great Sandy, and Great Victoria—cover the central part of the Western Plateau. All the deserts except the Gibson consist of swirling sands, which often drift into giant dunes. Some dunes measure more than 200 miles (320 kilometers) long. The Gibson Desert lies outside the path of the general wind direction and of wind-blown sands. Its surface consists of a mass of small stones and pebbles.

Rivers are one of Australia's most vital resources. Rivers provide the towns and cities with drinking water, and they supply farmers with much-needed water for irrigation. However, most of Australia's rivers are dry at least part of the year. They fill with water only during the rainy season. The rainy season occurs in summer in northern Australia, and in winter in southern Australia. Dams and reservoirs on all the largest rivers store water for use during the dry season.



The Murray River is Australia's longest permanently flowing river. The Murray River starts in the Snowy Mountains and winds west 1,609 miles (2,589 kilometers). It empties into the ocean southeast of Adelaide. During the southern dry season, the Murray is fed by the country's longest river, the Darling. The Darling River begins in the central part of the Eastern Highlands and flows southwest 1,702 miles (2,739 kilometers) to the Murray. The Darling is dry along most of its course in the winter. Its flow increases in summer, when the

Ayers Rock (called *Uluru* in Aboriginal), a popular tourist attraction, stands in Uluru-Kata Tjuta National Park in central Australia. The rock is about 1 $\frac{1}{2}$ miles (2.4 kilometers) long. It rises 1,142 feet (348 meters) above the desert floor and 2,844 feet (867 meters) above sea level. It has many small caves. The walls of many caves are covered with rock paintings made long ago by Aboriginal artists.

northern and central parts of the Eastern Highlands receive most of their rain. The Darling thus supplies the Murray when most of the other rivers in southern Australia dry up.

Australia's biggest water conservation project is the Snowy Mountains Scheme. It consists of an extensive system of dams, aqueducts, and tunnels. Some of the aqueducts and tunnels carry water from melting snows in the Snowy Mountains to nearby dams. The dams store the water. Other aqueducts and tunnels channel water from the dams into the Murray and Murrumbidgee rivers. The increased flow of water in these rivers is used to irrigate cropland in New South Wales and Victoria. Hydroelectric plants at the dams supply New South Wales, Victoria, and the Capital Territory with a little of their electric power. Tasmania draws almost all of its electric power from hydroelectric facilities.

Lakes. Australia's only large permanent lakes have been artificially created. They include Lake Argyle in Western Australia and Lake Gordon in Tasmania. Both are reservoirs for water conservation projects.

Most of Australia's natural lakes are dry for months or years at a time. Dry lakes called *playas* are common in South Australia and Western Australia. Most of the time, a playa is simply a dry bed of salt or clay. The playa fills with water only after heavy rains. Many playas lie in areas of extremely light rainfall and so may remain dry for years. The largest playas are in South Australia. They include Lake Eyre, Lake Torrens, Lake Gairdner, and Lake Frome.

Underground water. Australia has fairly plentiful underground water. But most of it is too salty for people to drink or for use as irrigation water. In many areas, however, the water is not too salty for livestock to drink. On many large cattle and sheep stations, underground wells supply all the drinking water for the animals.

Much of Australia's underground water is *artesian* water. Artesian water is trapped under such great pressure that it gushes to the surface through any opening. The water can thus be brought to the surface merely by digging a well. It does not have to be pumped.

Australia's chief source of artesian water is a vast underground rock formation called the *Great Artesian Basin.* The basin extends across much of eastern Australia. Other artesian basins lie near the northwest, west, and south coasts. Most of the water in the Great Artesian Basin is quite salty and so can be drunk only by livestock. In general, the water in the coastal basins has less salt. Some of this water is used for irrigation. Adelaide, Perth, and many smaller communities get some drinking water from coastal basins.

The Great Barrier Reef is the world's largest coral reef and one of Australia's most popular tourist attractions. Although its name suggests one reef, the Great Barrier Reef is a chain of more than 2,500 reefs. It also includes many small islands. The reefs and islands extend in a nearly unbroken chain for about 1,400 miles (2,300 kilometers) along Australia's northeast coast. The reefs are composed of about 400 species of corals of many shapes and colors. The waters around the Great Barrier Reef are warm the year around. The warm waters and the beauty of the coral formations attract swimmers and skin divers. The Great Barrier Reef area has a number of tourist resorts.

© Carl Roessler

The Great Barrier Reef, the world's largest coral reef, extends about 1,400 miles (2,300 kilometers) along Australia's northeast coast. Its beauty attracts many skin divers.

The unequal distribution of rainfall throughout Australia is a major feature of the country's climate. The interior is dry most of the year and comes to life only after a heavy rain, *left.* Rain forests along the northeast coast receive plentiful moisture and are green all year, *right.*

Climate

The northern third of Australia lies in the tropics and so is warm or hot the year around. The rest of the country lies south of the tropics and has warm summers and mild or cool winters.

In winter, many parts of the south have occasional frosts. But the Australian Alps and the interior of Tasmania are the only areas of the country where temperatures remain below freezing for more than a day or so at a time.

Australia receives most of its moisture as rain. Snow falls only in Tasmania and the Australian Alps. About a third of the country is desert and receives less than 10 inches (25 centimeters) of rain a year. The deserts are too barren even for the grazing of livestock. Much of the rest of Australia has less than 20 inches (51 centimeters) of rainfall annually. Few crops can be grown in these regions without irrigation. The heaviest rainfall occurs along the north, east, southeast, and extreme southwest coasts.

The east coast of Queensland is the wettest part of the continent. Some places along this coast receive as much as 150 inches (381 centimeters) of rain a year. Parts of the southeast coast and of Tasmania are the only areas of the continent that receive uniform amounts of rainfall the year around. Rainfall is seasonal throughout the rest of Australia.

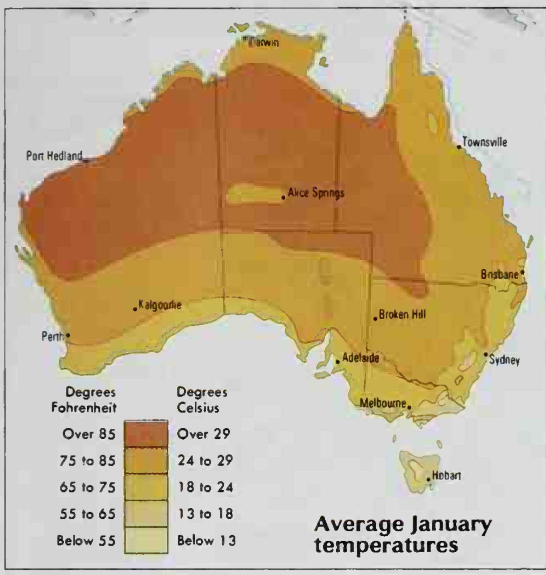
Australia lies south of the equator, and so its seasons are opposite those in the Northern Hemisphere. The

WORLD BOOK map

What Australia's climate is like

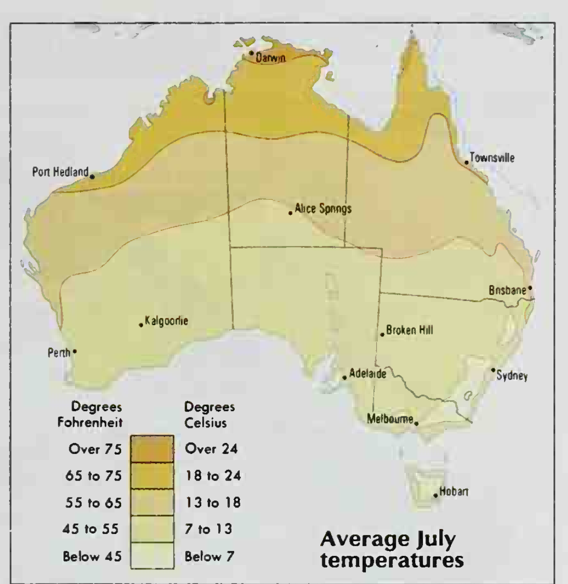
In general, Australia has a warm, dry climate. But the climate differs from one part of the country to another, as this map shows. Australia lies south of the equator, and so its seasons are opposite those in the Northern Hemisphere.

Tropical Wet and Dry: Always hot; alternate wet and dry seasons; heavy precipitation in summer.



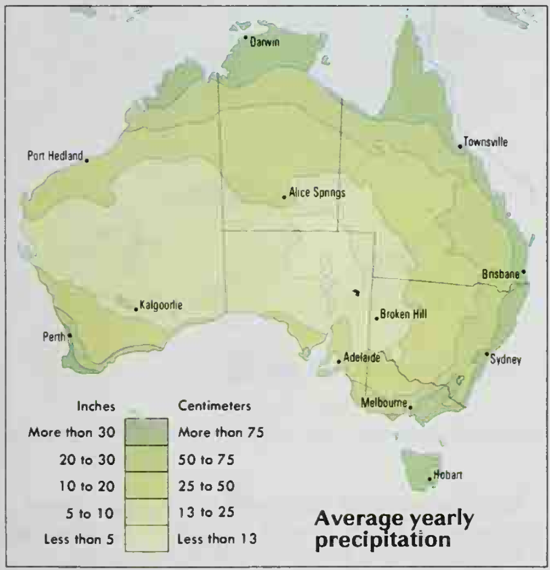
Semiarid: Hot summers; mild winters; great changes in daily temperature; light precipitation.

Desert: Hot to cool; great changes in daily temperature except in coastal areas; little precipitation.



Subtropical Moist: Warm to hot summers; warm or mild winters; moderate precipitation.

Oceanic Moist: Moderately warm summers; generally cool winters; moderate precipitation.



Subtropical Dry Summer: Hot, dry summers; mild winters; moderate precipitation in winter.

This map shows the average temperatures in Australia during January, midway through the country's summer. Australia's summers are hottest in the northwest and coolest in the southeast.

July is the coolest month in every part of Australia. Light frosts are common in the south during July. But the extreme southeastern highlands are the only areas that ever have cold weather.

This map shows the average amounts of annual precipitation in Australia. Almost all the precipitation is in the form of rain. Snow falls only in the extreme southeastern highlands.

David Moore, Black Star

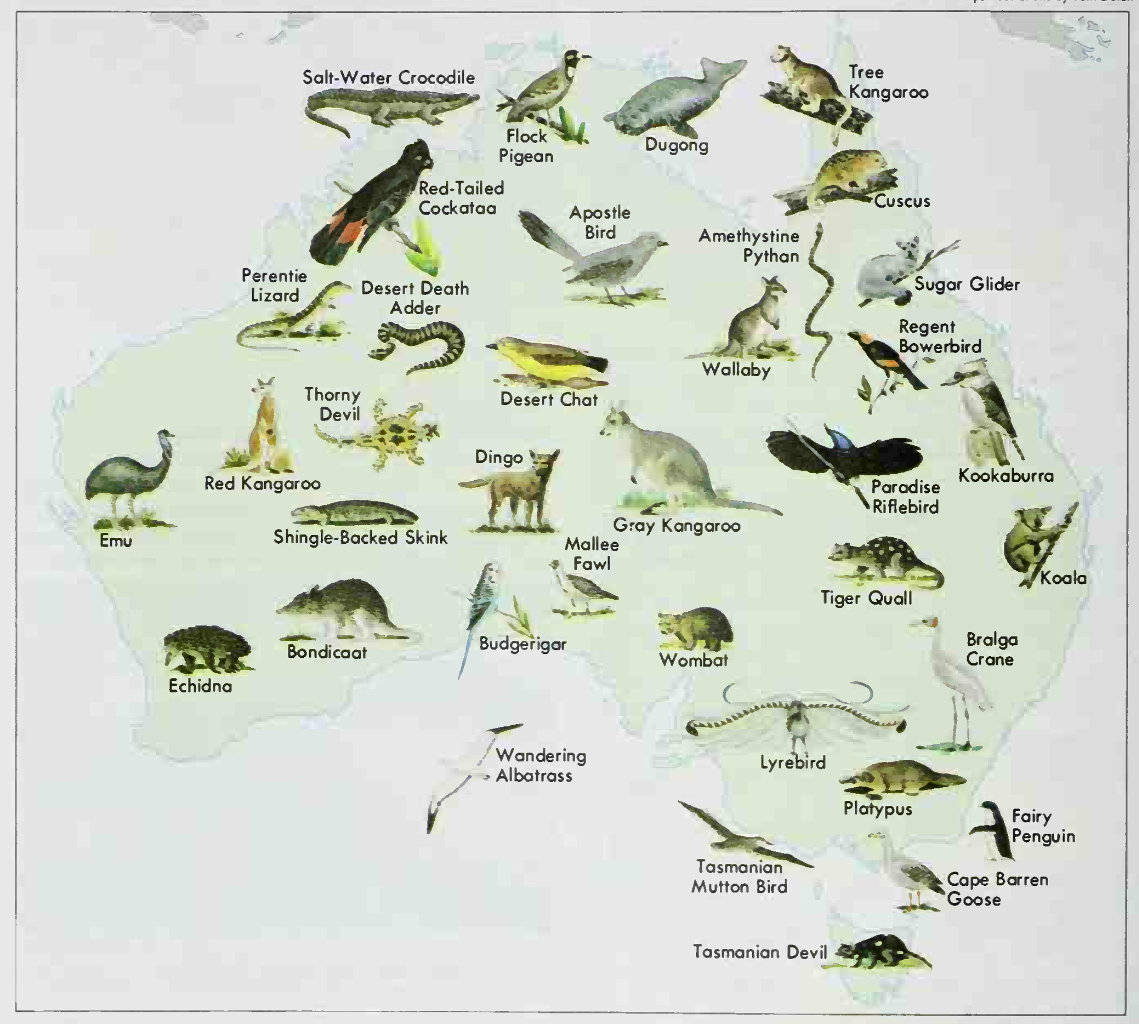
Snow covers Mount Kosciusko, *above,* and other peaks in the Australian Alps in winter. The area attracts many skiers.

southern part of the continent has four distinct seasons. Winter, the wettest and coolest season in Australia, lasts from June through August. Summer, which is the hottest and driest season, lasts from December through February.

Tropical northern Australia has only two seasons—a wet season and a dry one. The wet season corresponds with summer and lasts from November through April. The dry season corresponds with winter and lasts from May through October.

The wet season brings heavy downpours and violent storms, especially on Australia's north coast. In 1974, for example, a cyclone almost leveled the northern coastal city of Darwin. Floods plague many parts of Australia during the wet season. However, droughts are usually a far more serious problem. Nearly every section of Australia has a drought during the country's annual dry season.

Water conservation measures prevent these droughts from doing serious harm in most cases. However, Australia also has periods when little or no rain falls even during the wet season. These droughts can cause severe water shortages.



Animals and plants

Native animals. At one time, all the continents were part of one huge land mass. Australia became separated from this land mass about 200 million years ago. As a result, its animals developed differently from those on other continents. Australia's most famous native animals include kangaroos, koalas, wallabies, wombats, and

Animals of Australia

Some of the many mammals, birds, and reptiles of Australia are pictured on the map below. The animals live in various other areas on the continent in addition to those indicated. For example, emus live everywhere in Australia except the rain forests.

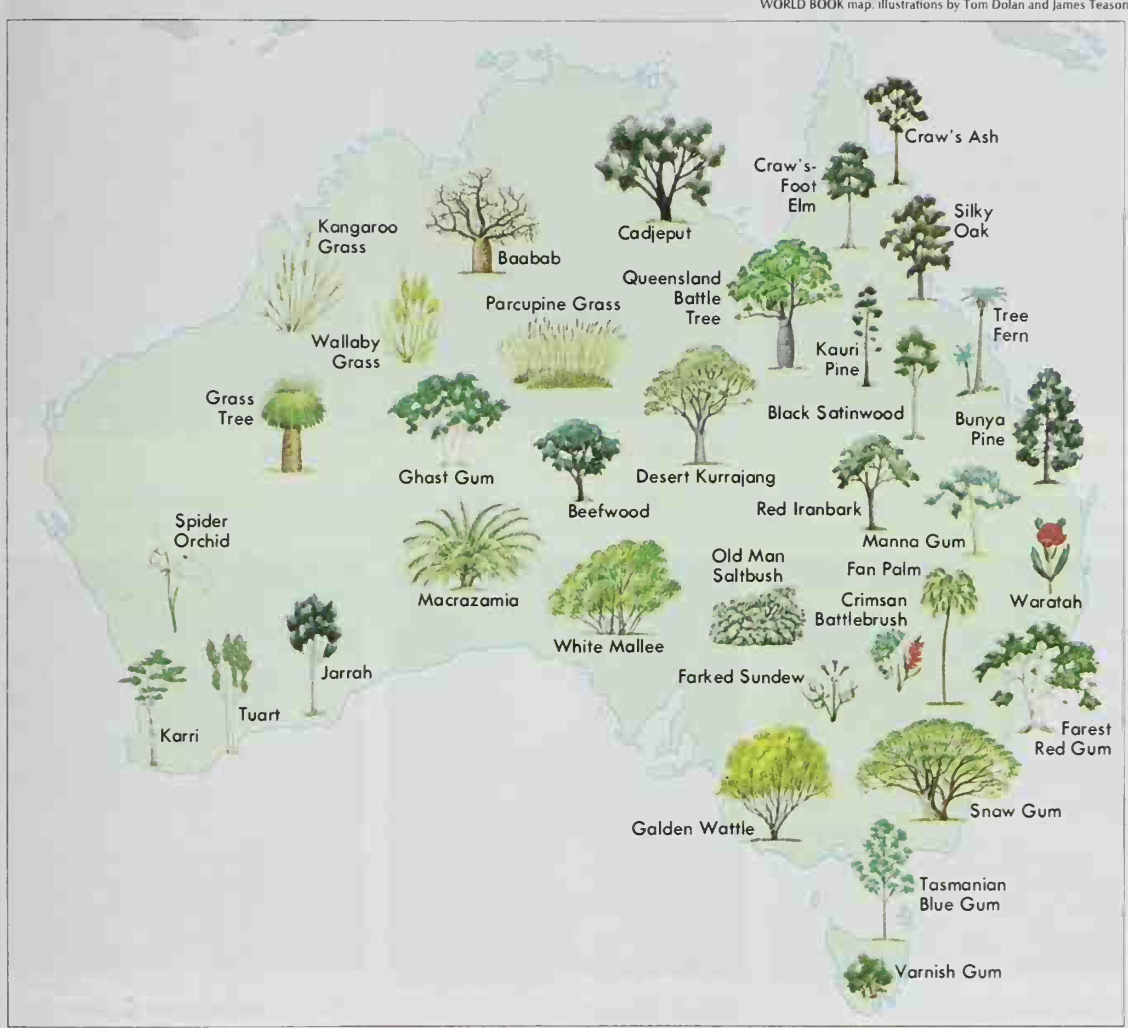
WORLD BOOK map; illustrations by Tom Dolan

other *marsupials.* Marsupials are mammals that give birth to tiny, poorly developed offspring. In most species, the babies mature in a pouch on the mother's abdomen. Australia has about 150 species of marsupials, all of which have pouches. One or more species live in every part of the country.

The platypus and the echidna are among the strangest Australian animals. They are the only mammals that hatch their young from eggs. Platypuses live only in Australia. Echidnas live in Australia and on the neighboring island of New Guinea.

Australia has about 700 species of native birds. They include the world's only black swans and about 60 kinds of cockatoos, parakeets, and other parrots. Two large flightless birds, the emu and the cassowary, are also native to Australia. The kookaburra, a member of the kingfisher family, is one of Australia's best-known birds. Its loud, harsh call is a familiar sound in residential areas.

Australia has about 140 species of snakes and about 370 species of lizards. Most of the snakes are poisonous. In fact, two of them, the taipan and the tiger snake, are among the deadliest snakes in the world. All the lizards are nonpoisonous.



Native plants. Two main kinds of native plants, *acacias* and *eucalyptuses,* dominate Australia's landscape. They are the most common shrubs in the dry lands and the most common trees in the moister areas. Acacias, which Australians call *wattles,* bear their seeds in pods. Australia has about 700 species of acacias. Many of them have brightly colored flowers. Common shrubby species include the mulga and the myall. The silver wattle and the blackwood are tall trees.

Eucalyptuses—or *eucalypts,* as they are known in Australia—are the most widespread plants in the country. Australia has about 500 species of eucalyptuses. Most species have narrow, leathery leaves. The leaves

Plants of Australia

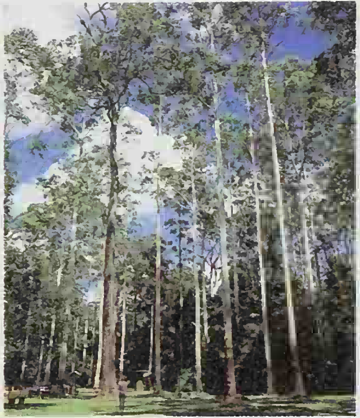
This map pictures some of the trees, shrubs, and other plants of Australia. Many of the plants, such as wallaby grass and golden wattles, grow in other areas of the continent in addition to those shown. However, forest trees grow only in the moist coastal regions.

WORLD BOOK map, illustrations by Tom Dolan and James Teason

contain a fragrant oil, which gives the plants a noticeable odor. Scrubby eucalyptuses, which are known as *mallees,* cover large areas of the interior. Eucalyptus trees, which Australians call *gum trees* or *gums,* are the tallest trees in the country and among the tallest in the world. Two species, the mountain ash and the karri, may grow to about 280 feet (85 meters). Eucalyptuses once grew only in Australia and on a few islands to the north. However, eucalyptuses have been planted in many other warm areas, including California, Hawaii, and countries bordering the Mediterranean Sea.

Palms and trees that resemble palms grow in many parts of Australia. Grass trees are palmlike trees of the western dry lands. They are related to the yucca trees of the American Southwest. Macrozamia trees grow throughout Australia. They have palmlike or fernlike leaves and bear cones, like needleleaf trees. Australia has few native needleleaf trees, other than kauri pines and bunya pines. Shrubs called *saltbushes* are common in the dry grazing areas of southern Australia. They are so named because their leaves have a salty taste. The leaves are excellent feed for livestock.

Australia has thousands of wildflowers. Many of them are desert species whose seeds lie buried until brought to life by a heavy rain. Then, for a few days or weeks, the desert is carpeted with flowers of every color.



Introduced species. The only mammals that lived in Australia before the first settlers arrived were bats, echidnas, mice, platypuses, rats, and the various kinds of marsupials. The first settlers, the Aborigines, brought along a type of dog known as a *dingo.* Some dingoes escaped into the wild. Today, their descendants are Australia's chief beasts of prey. European settlers introduced into Australia many familiar mammals, including cats, cattle, deer, foxes, goats, horses, pigs, rabbits, and sheep. They also introduced such animals as camels and

water buffaloes, various kinds of birds, and many species of plants.

Camels, cane toads, water buffaloes, and certain other introduced species have become wild and are pests. In some cases, species have had to be exterminated. Wild rabbits, for example, cause extensive damage to crops and grazing lands. In the 1950's, a drive to wipe them out with a deliberately introduced disease, myxomatosis, met with considerable success. But then the rabbits developed *immunity* (natural protection from the disease), and their numbers began increasing again. In the mid-1990's, scientists released a new virus, *Calicivirus,* that has helped control the number of rabbits.

Economy

Australia is one of the world's rich, developed countries. Most developed countries have become rich through the production and export of manufactured goods. Unlike other developed countires, Australia has

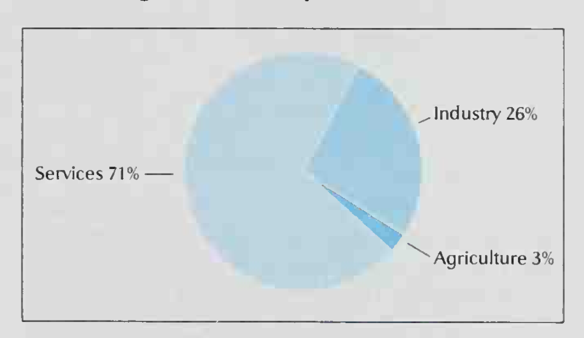
Nick Rains, Australian Picture Library

Assembly plants, such as this automaking plant in the Melbourne suburb of Broadmeadows, account for much of Australia's industrial output. Many other plants process farm products or minerals.

become wealthy chiefly through farming and mining.

The processing of farm and mineral products is a major part of Australia's manufacturing industry. For many years, manufacturing was the leading employer in Australia. But in the late 1900's, manufacturing declined in importance, while service industries rose in importance.

The nation relies on its farms and mines to produce goods for export. By selling farm products and minerals abroad, Australia earns the export income that most other developed countries earn from the sale of manufactured products. But only part of Australia's export income goes to the farmers and mining companies that produce the goods. Much of it goes to firms that process and distribute the goods. Thus, agricultural and mineral exports benefit the economy as a whole and enable many Australians to have a high standard of living.



Australia has traditionally been handicapped by a lack of *capital*—that is, money to finance business and industrial development. As a result, the country has had to borrow capital from other nations and has accumulated large debts. Many mining companies, factories, and other businesses in Australia are owned or controlled by American, British, Japanese, and other foreign investors.

Service industries are the economic activities that provide services, rather than produce goods. Service industries provide nearly three-fourths of Australia's jobs and make up more than two-thirds of Australia's *gross domestic product*—the total value of goods and services produced within the country annually.

Hospitals, schools, government agencies, stores, hotels, and restaurants are service industries. Also included in this category are banking, trade, transportation, and communication and tourism activities.

Manufacturing. Unlike most other developed countries, Australia imports more manufactured goods than it exports. Australian factories produce many of the *consumer goods,* such as processed foods and household articles, that the people require. But the nation has to import most of its *producer goods*—that is, factory machinery, construction equipment, and other goods used in production. Iron and steel are the chief exceptions. Australia's iron and steel industry produces enough of

Australia's gross domestic product

Australia's gross domestic product (GDP) was $364,511,000,000 in U.S. dollars in 1998. The GDP is the total value of goods and services produced within a country in a year. *Services* include community, government, and personal services; finance, insurance, and real estate; transportation and communication; and wholesale and retail trade. *Industry* includes construction, manufacturing, mining, and utilities. *Agriculture* includes agriculture, forestry, and fishing.

Production and workers by economic activities

Economic activities	Percent of GDP produced	Employed workers: Number of people	Employed workers: Percent of total
Finance, insurance, real estate, & business services	27	1,247,400	15

Mining and manufacturing in Australia

This map shows the location of Australia's chief mineral deposits and manufacturing centers. Most of the mineral deposits are mined, and so they are the centers of Australia's mining industry. Major deposits are shown in large type, and lesser ones in small type. Manufacturing centers are in red.

WORLD BOOK map

the metals to meet the needs of other industries. Australia's factories depend heavily on foreign capital.

Most of Australia's factories specialize in assembly work and light manufacturing. Many plants process farm products or minerals for export. The leading manufactured products are processed foods; metals, including iron and steel; transportation equipment, including automobiles; paper; printed materials; chemicals; textiles, clothing, and shoes; and household appliances. New South Wales and Victoria are the chief manufacturing states. Together, these two states have about two-thirds of the country's factories and about two-thirds of the factory workers. Most of the factories are located in and around Sydney and Melbourne.

Mining. Australia has rich mineral resources. But many of the deposits lie in the dry areas, far from major settlements. Such deposits are extremely expensive to mine. Roads and railroads have to be constructed to the mining sites. The miners and their families must have housing. The costs of mining development in Australia are so high that the mining industry depends heavily on foreign capital. Foreign investors own or control about half of the mining industry. In 1975, the Australian federal government established a general rule that at least 50 percent of every major new mining operation in the country should be owned by Australian investors. However, the government does not strictly enforce this rule if the Australian capital needed for the mining operation is unavailable.

Australia began to develop its mineral resources during the 1800's. By the end of the century, it was exporting large amounts of copper, gold, lead, silver, tin, and zinc. These minerals remained the chief products of the mining industry until the mid-1900's. During the 1950's, geologists discovered huge deposits of bauxite, coal, and iron ore in Australia. They discovered manganese, natural gas, nickel, and petroleum during the 1960's.

Australia has become one of the major mining countries of the world. It ranks first in the production of bauxite, diamonds, and lead. In addition, it is a leading producer of coal, copper, gold, iron ore, manganese, nickel, silver, tin, titanium, zinc, and zircon. Nearly all of the

Australia's thriving mining industry produces large amounts of bauxite, coal, copper, diamonds, iron ore, lead, opals, and zinc. This iron ore mine is near Iron Knob, South Australia.

Agriculture and fishing in Australia

This map shows Australia's chief agricultural and fishing regions. The most fertile cropland lies along the east, southeast, and extreme southwest coasts. Dry grasslands cover much of the interior and are used to graze livestock. Shellfish are Australia's leading fishery products.

WORLD BOOK map

world's high-quality opals are mined in Australia.

Western Australia, Queensland, and New South Wales, in that order, are the leading mining states. Western Australia produces most of the nickel, iron ore, and gold and much of the bauxite. Queensland is the chief producer of bauxite, copper, and silver. New South Wales leads in the production of coal, lead, and zinc. All the manganese is mined in the Northern Territory. Most of Australia's tin comes from Tasmania. Offshore fields along the northwest coast of Western Australia are Australia's main source of petroleum. Other major petroleum producers include South Australia and Victoria. Natural gas is produced mainly in South Australia and the northwest coastal shelf of Western Australia. The country has the world's largest undeveloped deposits of uranium. The richest uranium deposits are located in the Northern Territory and South Australia.

Agriculture. Australia's farms are highly mechanized and thus require a minimum of human labor. Only about 5 percent of the country's workers are farmers. How

The Snowy Mountains Scheme is a vast irrigation and hydroelectric power project in Australia's southeastern highlands. Pipelines like those at the left carry water from mountain streams to a nearby series of dams and hydroelectric plants. The runoff from the dams flows into the Murray and Murrumbidgee rivers for use in irrigation.

Golden wheat fields, such as this one in New South Wales, are important to the Australian economy. Australia exports great quantities of wheat to China, Japan, and other Asian countries.

© Lance Nelson, Stock Photos

ever, they produce nearly all of the food the people need.

Farmland covers about 60 percent of Australia. However, most of this land is dry grazing land. Crops are grown on only about 10 percent of the farmland. But farmers use modern agricultural methods and so make the cropland highly productive. About 10 percent of the cropland is irrigated.

Australia's leading farm products by far are cattle and calves, wheat, and wool, followed by dairy products, fruits, and sugar cane. These products are also the country's chief agricultural exports. Australia is the world's largest producer and exporter of wool and a leading producer and exporter of beef, sugar, and wheat. A rapidly growing industry is winemaking. The country's other major farm products include barley, chickens and eggs, oats, rice, potatoes, sheep and lambs, vegetables, and cotton.

Sheep and cattle are raised in all the Australian states, though some states raise far more than others. New South Wales and Western Australia together raise more than half the country's sheep and produce about half its wool. Queensland and New South Wales raise more than half of Australia's beef cattle. Victoria is the leading producer of dairy products.

Wheat is grown in all areas of the country that have medium rainfall and moderate temperatures. But production is heavily concentrated in New South Wales and Western Australia. Farms on the east coast of Queensland grow sugar cane, bananas, pineapples, and other crops that need a wet tropical climate. Such fruits as apples and pears are grown in all the states. New South Wales and South Australia produce most of the country's oranges.

Forestry and fishing. Forests cover about 20 percent of Australia. Nearly all of them grow in the Eastern Highlands and in the moist coastal areas. The northeast coast has tropical rain forests. The vast majority of Australia's forest trees are eucalyptuses. The wood of some eucalyptus species is used for making paper and such items as floorboards and furniture. But eucalyptus wood is too hard for most other purposes, including most types of housing construction. Therefore, imported species of softwoods have been planted on tree farms. Monterey pines, which were imported from California, have become Australia's second most important timber trees, after eucalyptuses.

Although Australia is surrounded by water, its fishing resources are limited. Thousands of species of fishes live in the coastal waters. However, only a few are both plentiful and good to eat. Nevertheless, Australia has developed a small but profitable fishing industry. The industry earns most of its income from the catch of shellfish, especially abalones, lobsters, oysters, prawns, and scallops. In addition, the fishing fleet brings in fairly large catches of mullet, salmon, and tuna. Much of the shellfish catch is exported. Some pearls are collected from oysters.

Tourism. Australia has a variety of tourist attractions. They include wildlife sanctuaries, sandy beaches, the Great Barrier Reef, the Australian Alps, and numerous points of historical interest. More than 4 million foreign tourists visit Australia each year. Tourism aids the economy.

Distance and cost have been the major obstacles to growth of Australia's tourist industry. Australia is about twice as far from North America and Europe as North America and Europe are from each other. Travel between Europe and North America is therefore less costly than it is between Europe or North America and Australia. About half of Australia's visitors come from less distant places, especially New Zealand and other Pacific islands, Japan, and Southeast Asia. These places are also the ones most visited by Australians.

International trade. Farm products, minerals, and other raw materials account for about half of Australia's export earnings. Manufactured goods account for approximately one-third of such earnings. More than three-fourths of Australia's imports are manufactured goods.

© Robert Frerck

Beef cattle are raised throughout Australia except the deserts. But production is greatest in New South Wales and Queensland. This cattle auction is being held in Rockhampton, Queensland.

For many years, the United Kingdom (U.K.) was Australia's chief trading partner. The British bought Australian farm products and supplied Australia with producer goods. During the 1960's, the U.K.'s trade with Australia began to decline. Australia still exports minerals, wheat, and fruits to the U.K. and other Western European countries. But today, Japan is Australia's biggest customer. It especially buys coal, iron ore, and other minerals. China, Japan, and other Asian countries have become major purchasers of Australian farm products, especially wheat. Japan is by far the leading buyer of Australian wool. The United States and Japan have replaced the U.K. as Australia's chief source of producer goods. The United States, in turn, imports large amounts of Australian beef, shellfish, sugar, and *alumina*—the substance in bauxite that is used to make aluminum.

Transportation. Automobiles are the chief means of passenger transportation in Australia. Nearly every family owns a car and uses it for most local travel. Paved highways link the state capitals and the largest inland cities. Most roads in the outback are unpaved.

Qantas (Queensland and Northern Territory Aerial Services Ltd.) is Australia's largest domestic airline and its main international airline. Many foreign airlines also fly between Australia and major cities throughout the world. Sydney, Melbourne, Brisbane, Cairns, and Perth have large international airports. Air transportation is particularly important in the outback. A private, nonprofit organization called the Royal Flying Doctor Service flies emergency medical help to all areas of the outback except the Northern Territory. A publicly owned company provides this service in the Northern Territory.

Trucks, railroads, and ships haul most of Australia's intercity freight. The trucking industry is mainly privately owned. Australia's main-line railroads were all publicly owned until the late 1900's, but many are now privately owned. The Trans-Australian Railroad is the country's longest rail line. It extends 1,108 miles (1,783 kilometers) from Port Pirie in South Australia to Kalgoorlie in Western Australia. The main-line railroads chiefly haul farm goods and minerals from the producing areas to the coastal cities and ports. In addition to the main rail lines, Australia has several small private railroads. These lines largely haul minerals from out-of-the-way mines to the main-line railroads. Sydney and Melbourne have extensive commuter rail and subway systems.

Ships carry large amounts of minerals between Australian coastal ports, and they haul nearly all the country's overseas freight. However, Australia has only a small merchant fleet. Foreign vessels carry most of the nation's intercoastal freight and almost all its overseas cargo. The busiest eastern ports include Gladstone, Hay Point, Melbourne, Newcastle, and Sydney. Dampier, Fremantle, Port Hedland, and Port Walcott are among the busiest ports in Western Australia.

Communication. Australia's postal, telephone, and telegraph systems are partly or fully owned by the federal government and operated by independent government agencies. The Australian Postal Corporation runs the postal system. The telephone system was fully government-owned until the 1990's. But the telecommunications industry now operates in a competitive market. Telstra, a partially government-owned company, is the biggest operator. Except in the outback, nearly every Australian household has a telephone. In the remotest parts of the outback, many people use two-way radios instead of telephones. The Internet has become an important means of communication throughout Australia. Most Australian homes have at least one computer.

Almost all Australian families own one or more television sets and radios. Commercial broadcasters own and operate about half the radio stations and three of the five free TV stations. Almost all the rest are owned and financed by the federal government and operated by the Australian Broadcasting Corporation (ABC), an independent government agency. Unlike the commercial stations, the ABC stations accept no advertising.

Australia has approximately 50 daily newspapers, all of which are privately owned. Every big city has at least one daily paper. The most widely read daily newspapers in the country include Melbourne's *Herald Sun* and *The Age* and Sydney's *Morning Herald* and *Daily Tele-*

The Royal Flying Doctor Service provides emergency medical services to people living in remote areas of Australia. Air transportation is vital in the Australian outback.

graph. A national daily, *The Australian,* is published in Sydney, Melbourne, Adelaide, and Brisbane.

History

Australia's first settlers were ancestors of today's Aborigines. They may have reached the continent as early as 65,000 years ago and came from Asia by way of New Guinea. When the first whites arrived in 1788, about 750,000 Aborigines lived in Australia.

European discovery. The European discovery of Australia began with the discovery of New Guinea by Portuguese and Spanish explorers during the 1500's. These explorers and others after them were searching for a mysterious continent believed to lie south of Asia. The continent was known as *Terra Australis Incognita,* a Latin term meaning *Unknown Southern Land.*

In 1606, a Spanish explorer named Luis Vaez de Torres proved that New Guinea was not the unknown continent. He sailed through the strait between New Guinea and Australia and so showed New Guinea to be an island. However, Torres had no idea that a vast continent lay only about 100 miles (160 kilometers) to the south. Also in 1606, a Dutch navigator named Willem Jansz sailed along and briefly visited what he thought was a coast of New Guinea. Actually, it was the west coast of Cape York Peninsula in extreme northeastern Australia. Jansz thus became the first European known to sight the continent and land in Australia.

From 1616 to 1636, other Dutch navigators explored Australia's west, southwest, and northwest coasts. Explorers then began to believe they had found the mysterious southern continent. In 1642 and 1643, Abel Janszoon Tasman, a Dutch sea captain, sailed around the continent without sighting it. During his voyage, Tasman saw and briefly visited a land mass that he named *Van Diemen's Land.* He originally thought that this land was part of the continent. But actually, it was an island, which was renamed *Tasmania* in his honor in 1855.

All the early explorers reported unfavorably on what they had seen of Australia. The land was dry and barren, and the people had no gold or other riches. Then, in 1770, James Cook of the British Royal Navy became the first European to sight and explore Australia's fertile east coast. Cook claimed the region for the United Kingdom and named it *New South Wales.*

Early settlement. Before the Revolutionary War in America, the United Kingdom regularly shipped many convicts to its American colonies. This practice, which was known as *transportation,* helped relieve overcrowding in British jails. After the United States won its independence in 1783, the United Kingdom had to find a new place to transport convicts. In 1786, the British decided to start a prison colony in New South Wales. Captain Arthur Phillip, a retired naval officer, was appointed to establish the colony and serve as its governor.

In May 1787, Phillip sailed from England with about 570 male and 160 female convicts, about 200 British soldiers to serve as guards, about 30 wives of soldiers, and a few children. The group traveled in 11 ships. The first ship reached Botany Bay, on Australia's east coast, on Jan. 18, 1788. Phillip set up the colony's first settlement by a large harbor about 7 miles (11 kilometers) north of Botany Bay. It was the first white settlement in Australia and the beginning of the city of Sydney.

The new colony had to support itself by farming. The convicts worked on community farms near the settlement. During the 1790's, the colonial government began to grant land to military officers and freed convicts, and free settlers began arriving from the United Kingdom.

Exploring the new land. When New South Wales was first settled, people did not know if Australia consisted of one huge land mass or of two or more large islands. The northwestern, western and southwestern coastline had been thoroughly mapped, and so it was known that all western Australia formed one land mass. Tasman had named this land New Holland. The east coast of Australia was mapped after Cook discovered it. But much of the southern coastline and part of the northern coastline remained uncharted. People therefore thought that New South Wales and New Holland might be islands rather than parts of one continent.

In 1798 and 1799, two British navigators, George Bass and Matthew Flinders, sailed around Tasmania and so proved it to be an island. From 1801 to 1803, Flinders

Engraving (1865) based on a wood engraving by John Alexander Gilfillan, *Illustrated Melbourne Post,* December 1865; National Library of Australia

James Cook explored Australia's fertile east coast in 1770 and claimed it for the United Kingdom. Cook's expedition largely completed the European discovery of Australia, which had begun during the early 1600's.

Important dates in Australia

65,000 years ago Ancestors of the Aborigines may have settled Australia.
A.D. 1606 Willem Jansz became the first European known to sight Australia and land there.
1642 Abel Janszoon Tasman sighted Van Diemen's Land. It was renamed Tasmania in 1855.
1770 James Cook explored Australia's east coast. He claimed the area for the United Kingdom and named it New South Wales.
1788 The United Kingdom established New South Wales as a prison colony.
1801-1803 Matthew Flinders sailed completely around Australia, proving it to be one large land mass.
1829 Charles Fremantle claimed the entire western part of the Australian continent for the United Kingdom.
1851 Gold was discovered in New South Wales and Victoria.
1868 The United Kingdom ended the transportation of convicts to Australia.
1901 Australia became an independent nation. Melbourne was named the temporary capital.
1927 The federal capital was transferred to Canberra.
1967 The Australian Constitution was amended to permit the establishment of federal programs to aid the Aborigines.
1978 The Northern Territory became responsible for its own administration, the first step toward Australian statehood.
1999 Voters rejected a plan to make Australia a republic and chose to keep the British monarch as Australia's head of state.

sailed around the continent and mapped all the uncharted areas of the southern coastline. This proved the mainland to be one land mass. There could no longer be any doubt that this land mass was *Terra Australis,* the southern continent. By the 1820's, *Australia* had become its generally accepted name.

The settlers in New South Wales explored the area around Sydney during the early 1800's. In 1824, Hamilton Hume and William Hovell opened up an overland route from Sydney to the future site of Melbourne. On their way, they sighted an exceptionally broad river. In 1829 and 1830, Charles Sturt followed this river to its mouth, near what is now Adelaide. He thus paved the way for the establishment of the colony of South Australia in 1836. Sturt named the river the *Murray.*

Also in 1829, a British sea captain named Charles Fremantle landed on Australia's southwest coast and claimed the entire western part of the continent for the United Kingdom. Later that year, a group of about 70 English settlers officially established the colony of Western Australia and founded its capital, Perth.

The squatter period. During the 1820's, the people of New South Wales began to develop a strong economy based on the production of wool for export to the United Kingdom. The large profits that could be made from the wool trade encouraged more and more settlers to raise sheep for a living. But the government of New South Wales allowed settlers to buy or lease grazing land only within a limited area. All the land outside this area was considered government property. To raise sheep, many settlers began to occupy government land illegally. These illegal landholders became known as *squatters.* Squatters gradually won legal recognition and were granted long-term leases on their land. Some eventually became the biggest landholders in Australia.

During the 1830's, a number of sheep farmers mi-

Australia exploration and discovery

grated to southern New South Wales from Tasmania and the area around Sydney. They founded Melbourne and occupied the rich grazing lands south of the Murray River. They did so well that they asked Britain to make them a separate colony. The request was granted in 1851. That year, the part of New South Wales south of the Murray River became the new colony of Victoria.

Exploring the interior. The first long expeditions into the interior began during the 1830's. In 1839 and 1840, Edward John Eyre discovered the vast, dry salt lakes northwest of Adelaide. In 1860 and 1861, Robert O'Hara Burke and William Wills became the first white people to cross the continent from south to north. They died of starvation on the return journey south. John McDouall Stuart made the first round trip between the south and north coasts in 1861 and 1862.

The Australian gold rush. In 1851, gold was discovered in New South Wales. A few months later, an even richer gold field was discovered in Victoria. Thousands of prospectors from overseas rushed to the gold fields. Some became rich. But most did not find enough gold to pay their passage home. Many gold seekers stayed in Australia. As a result, the population soared from about 400,000 in 1850 to more than 1,100,000 in 1860.

The end of transportation. Britain stopped transporting convicts to the eastern colonies of Australia by the early 1850's. However, it continued to send them to Western Australia until 1868, when the practice was finally ended. Altogether, more than 160,000 convicts were sent to Australia from 1788 to 1868.

Political and economic developments. As the number of free settlers in Australia grew, so did the colonists' demands for self-government. By 1856, Britain had granted self-government to all the colonies except Western Australia. Each had its own elected legislature and government ministers, who controlled the colony's internal affairs. Britain continued to manage the foreign affairs and defense of the colonies. Meanwhile, squatters had settled the part of New South Wales north and west of Brisbane. In 1859, Britain created the colony of Queensland out of this area, with Brisbane as its capital.

By 1860, thousands of disappointed gold miners wanted to buy plots of land and take up farming. But most of the best farmland was held by squatters. However, the squatters' leases expired in 1861. During the early 1860's, the colonial legislatures passed laws to redistribute the squatters' land. These laws permitted individuals to select any small area of farmland they wanted, including land held by squatters, and buy it from the government on credit. To defeat these measures, many squatters hired people to buy up as much land as they legally could and turn it over to the squatters. The big landholders thus kept much of their land.

The birth of a new nation. All the Australian colonies had self-government by the 1890's. However, a growing number of Australians believed that the colonies would be better off as a single nation with a unified government. Without such a government, it would always be difficult for the colonies to deal with their common problems in an organized manner. The movement toward federation was also encouraged by a growing sense of national pride. The creation of a national folklore by such writers as Henry Lawson and Banjo Paterson helped strengthen this spirit.

In 1897 and 1898, a federal convention drew up a constitution for Australia. The people approved it in balloting during 1898 and 1899. Britain approved it in 1900. On Jan. 1, 1901, the six colonies became states of a new nation, the Commonwealth of Australia. The new nation kept the British monarch as head of state. The federal Parliament met at Melbourne until a site for a national capital could be selected and developed.

At first, Australia had three political parties—the Protectionist Party, the Free Trade Party, and the Labor Party. The Protectionists wanted high *tariffs* (taxes on imports) to protect Australian industries from foreign competition. The Free Traders wanted low tariffs or none. The Labor Party represented the labor unions. By 1909, Parliament had settled the tariff question in favor of some tariffs. The Free Traders joined the Protectionists to form the Fusion Party, the forerunner of today's Liberal Party. The National Party was founded in 1919. It was called the Australian Country Party from 1919 to 1975 and the National Country Party from 1975 to 1983.

World War I. When Britain declared war on Germany in 1914, Australia considered itself automatically at war on the side of Britain. More than 400,000 Australians served in the Australian armed forces before the war

In 1829, Western Australia became the third British colony in Australia. Britain had established New South Wales in 1788 and Van Diemen's Land in 1825.

In 1836 and 1851, Britain established two more colonies—South Australia and Victoria. The land for the new colonies was taken from New South Wales.

WORLD BOOK maps

By 1911, the map of Australia looked much as it looks today. Queensland and the mainland territories were set up. Van Diemen's Land was renamed Tasmania.

ended in 1918. During the war, a corps of Australian and New Zealand troops called *Anzacs* (*A*ustralian and *N*ew *Z*ealand *A*rmy *C*orps) won a reputation for outstanding bravery. About 59,000 Australians died in the war—the most deaths in proportion to total number of troops among all the Allies. The war is commemorated on Anzac Day, a national day of mourning on April 25.

Between the wars. Work on the new federal capital at Canberra continued after the war. Parliament had selected the site in 1908, and construction had begun in 1913. The capital was transferred from Melbourne to Canberra in 1927. The Great Depression, the worldwide business slump of the 1930's, had a disastrous effect on Australia's economy. Many wool, wheat, and sugar producers went bankrupt. In the worst of the depression, nearly a third of the country's workers had no job.

World War II. Australia entered World War II on the side of the British on Sept. 3, 1939. It sent troops to fight German forces in mainland Greece, Crete, and northern Africa. Many of these troops were brought back to Australia after Japan entered the war on Germany's side in December 1941. On Feb. 19, 1942, Japanese planes bombed Darwin. By early March, Japanese troops had landed in New Guinea and were threatening to invade Australia. This threat was removed by the U.S. show of strength in the Battle of the Coral Sea in May. From then until the war ended in 1945, Australia directed its military effort at driving the Japanese from New Guinea.

About 925,000 men and about 65,000 women served in Australia's armed forces during World War II. Over 29,000 Australians died in battle or as prisoners of war.

The postwar years. The Labor Party governed Australia from 1941 to 1949, when it was defeated in parliamentary elections. The Liberals won enough seats to form a government with the Country Party. Such Liberal and Country party *coalitions* held power until 1972.

Australia became a charter member of the United Nations (UN) in 1945 and began to play an increasingly active role in world affairs. The country contributed to the UN forces that fought in Korea from 1950 to 1953. In 1950, Australia helped create the Colombo Plan for economic development in southern and southeastern Asia. In 1951, Australia joined New Zealand and the United States in signing the ANZUS Treaty, a mutual defense agreement. From 1964 to 1972, Australian troops assisted the United States in the Vietnam War.

During the 1960's, Australia generally enjoyed economic growth and prosperity. It resulted chiefly from the discovery of vast mineral deposits in the 1950's and 1960's. The export of bauxite, coal, iron ore, and nickel added greatly to the country's income.

Political crisis. In 1972, the Labor Party came to power with a majority in the House of Representatives but not in the Senate. Gough Whitlam, the party leader, became prime minister. By 1975, inflation and unemployment were rising, and the Labor government had become unpopular. In October 1975, the Liberal and National parties used their Senate majority to threaten to stop the supply of money for day-to-day government operations. They hoped to force Whitlam to resign.

Whitlam refused to resign, and the opposition parties refused to assure the flow of government money. In November, the governor general, Sir John Kerr, resolved the crisis by removing Whitlam from office. Kerr named Malcolm Fraser, head of the Liberal Party, to serve as prime minister until new elections could be held. The Liberal and National coalition won elections in December 1975 and in 1977 and 1980. Fraser remained prime minister. The Labor Party regained power in elections in 1983. Party leader Robert Hawke became prime minister. The Labor Party won elections in 1984, 1987, and 1990.

Recent developments. Problems faced by Australia today include continuing inflation and unemployment, as well as a growing international debt. Australia's hopes for economic growth are closely tied to the growth of its mining industry. Uranium is Australia's most valuable undeveloped mineral resource. The uranium industry began to expand in the late 1970's, when the worldwide demand for uranium increased. However, Australians who oppose nuclear power because of its potential hazards also oppose plans to mine and export uranium. Also, some of the richest uranium deposits lie in the traditional tribal lands of the Aborigines.

In the early 1970's, vast fields of natural gas were discovered on the coast of Western Australia. Australia began developing the fields in 1980. It is the largest single-resource development project in Australia's history.

In 1989, the Australian government set up the Aboriginal and Torres Strait Islander Commission (ATSIC). Aborigines and Torres Strait Islanders elect the ATSIC to represent their interests and to manage many aspects of Aboriginal affairs. In 1992, the High Court of Australia,

in the case of *Mabo v. Queensland,* ruled that Aborigines and Torres Strait Islanders had legal title to their lands before European settlers took the land. Previous British and Australian law had said the land belonged to no one. The case helped establish the Aborigines' legal right, under certain conditions, to reclaim their lands.

In 1991, during a recession, the Labor Party members of Parliament voted to replace Hawke with Paul Keating as head of their party. As a result, Keating also replaced Hawke as prime minister. The Labor Party won parliamentary elections in 1993, and Keating remained in office. A coalition of the National and Liberal parties won general elections in 1996, 1998, and 2001. John Howard, the leader of the Liberal Party, served as prime minister.

During the 1990's, many Australians called for their nation to become a republic with a president replacing the British monarch as head of state. In 1998, a constitutional convention voted in favor of making Australia a republic by Jan. 1, 2001. In a 1999 referendum, however, Australian voters rejected the convention's plan to make Australia a republic and chose instead to keep the British monarch as head of state. D. N. Jeans and John Rickard

Australian Aborigines. See Aborigines, Australian.

Australian cattle dog is a breed of dog that originated in Australia during the 1800's. It was developed

from several breeds of farm dogs, including collies and kelpies. Farmers and ranchers use Australian cattle dogs to herd cattle. These dogs nip at the heels of the cattle to keep them from straying. The dogs also make excellent watchdogs and affectionate pets.

Australian cattle dogs stand from 17 to 20 inches (43 to 51 centimeters) high and weigh 35 to 45 pounds (16 to 20 kilograms). They have short, thick coats and bushy tails. Many of the dogs are blue and may have black, blue, or tan markings on the head, and tan markings on the chest and legs. Others are red, and many have red speckles all over the body. Puppies are born with white coats. Their color and markings appear in a few months. The Australian cattle dog has been known by several other names, including the *Australian heeler,* the *Queensland heeler,* the *Queensland blue heeler,* and the *blue heeler.* Critically reviewed by the American Kennel Club

See also **Dog** (picture: Herding dogs).

Australian Desert refers to three deserts that cover most of western and central Australia. The deserts are the Great Sandy Desert, the Gibson Desert, and the Great Victoria Desert. The three deserts are not as dry as most other deserts, and they have a thin cover of vegetation. The Great Sandy Desert stretches south to the Gibson Desert. It covers about 160,000 square miles (414,000 square kilometers). P. Egerton Warburton first walked over it in 1873. That same year, Ernest Giles became the first European to reach the 250,000-square-mile (647,000-square-kilometer) Gibson Desert. The Great Victoria Desert runs south from the Gibson Desert to the Nullarbor Plain (see **Australia** [physical map]). See also **Great Victoria Desert.** D. N. Jeans

Australian shepherd is a medium-sized dog that was originally bred for herding livestock. The breed was developed in the United States. It got its name because many sheepherders who came to the United States from Australia in the late 1800's used similar dogs to herd their flocks. Australian shepherds are often referred to as "Aussies." The Aussie stands 18 to 23 inches (46 to 58 centimeters) tall at the shoulders and weighs about 45 to 65 pounds (20 to 29 kilograms). It has a straight to wavy coat that may be blue or red *merle* (dark blotches against a lighter background of the same color), black, or red, often with white or tan markings. Aussies are intelligent, have protective instincts, and make good pets.

Critically reviewed by the United States Australian Shepherd Association

Paulette Johnson

The Australian shepherd has strong herding instincts.

Australian terrier is a small dog once used to guard mines and tend sheep in Australia. People now keep these terriers chiefly as pets. They have harsh, straight coats, with a soft-haired topknot on their heads. The coats may be blue- or silver-black, with tan markings on the head and legs. The dog weighs about 12 to 14 pounds (5.4 to 6.4 kilograms). The breed originated in Australia about 1885. See also **Dog** (picture: Terriers).

Australopithecus, *AW struh loh PIHTH uh kuhs,* is a group of species that most anthropologists regard as one of the earliest humanlike creatures. These species lived in Africa from about 4,000,000 years ago to between 2,000,000 and 1,000,000 years ago. Members of the *genus* (group of species) known as *Australopithecus* are called *australopithecines.* Australopithecine fossils include some of the oldest known *hominid* fossils. Hominids make up the scientific family of human beings and prehistoric humanlike species.

Australopithecines stood upright and walked on two legs. They were about 4 to 5 feet (120 to 150 centimeters) tall and had a brain about one-third the size of a modern human brain.

Most anthropologists recognize five species of *Australopithecus.* They are, in the order in which they appeared, *A. anamensis, A. afarensis, A. africanus, A. boisei,* and *A. robustus. A. boisei* and *A. robustus* had much larger jaws and teeth than the other species and are called robust australopithecines. The first three species are called *gracile* (slender) australopithecines. Most scientists believe human beings evolved from the gracile species. *A africanus* and *A. robustus* lived in southern Africa. The other three species lived in eastern Africa. The *Australopithecus* species were closely related to the earliest known hominid, *Ardipithecus ramidus,* which lived in what is now Ethiopia about 4,400,000 years ago.

Australopithecine fossils were first recognized in 1924 when South African anthropologist Raymond A. Dart identified a child's skull that had been found at Taung, near Vryburg, South Africa. Dart named the creature *Australopithecus africanus.* He believed it was a hominid, but most scientists thought it was an extinct ape. Additional fossils found during the next 35 years convinced scientists that *Australopithecus* was a hominid.

In 1974, researchers uncovered parts of the skeleton of a humanlike creature at Hadar, Ethiopia. The creature, nicknamed "Lucy," was about 3,200,000 years old. In 1978, researchers at Laetoli, Tanzania, found fossil footprints together with fossilized bones of a hominid that lived 3,600,000 years ago. These discoveries indicated that humanlike creatures had begun walking upright long before people began making stone tools about 2,500,000 years ago. Researchers have classified "Lucy" and the Laetoli fossils as *Australopithecus afarensis.* Australopithecine bones that may be those of *A. afarensis* have also been found in Chad, in north central Africa. In 1998, a complete *A. africanus* skeleton was found near Johannesburg, in South Africa. Alan E. Mann

A picturesque village nestles in a valley high in the Alps of western Austria. The ruins of a castle, *right,* overlook the village and the neat farmlands nearby. The majestic snow-capped Alps and their foothills cover most of Austria.

Austria

Austria is a small country in central Europe famous for its beautiful mountain scenery. The towering Alps and their foothills stretch across the western, southern, and central parts of the country. In many areas, broad, green valleys separate the mountains. Austria has many lovely, mirrorlike lakes. Thick forests cover much of the country's land.

Austria has no coastline. It shares boundaries with the countries of Switzerland and Liechtenstein to the west, Germany and the Czech Republic to the north, Hungary and Slovakia to the east, and Slovenia and Italy to the south. Vienna is the capital and largest city of Austria. It lies on the Danube River in the northeastern part of the country.

Most of Austria's people live in cities and towns. About a fifth of the people live in Vienna. Austrians enjoy good food, outdoor sports, and the arts. They take great pride in the fact that their country has long been a leading cultural center of Europe. The cultural institutions and scenic beauty of Austria attract millions of tourists each year.

Austria was once one of the most powerful countries in Europe. The royal Habsburg (or Hapsburg) family began to gain control of Austria in the late 1200's. In time, the country became the center of a huge empire that was ruled by the Habsburgs. This empire collapsed following the end of World War I in 1918. Austria then became a republic and went through a long period of economic difficulty and political unrest. During the last half of the 1900's, however, Austria became increasingly industrialized, and the economy of the country grew steadily. In addition, the country achieved political stability.

Facts in brief

Capital: Vienna.
Official language: German.
Official name: Republik Österreich (Republic of Austria).
Area: 32,378 mi² (83,859 km²). *Greatest distances*—east-west, 355 mi (571 km); north-south, 180 mi (290 km).
Elevation: *Highest*—Grossglockner, 12,457 ft (3,797 m) above sea level. *Lowest*—Neusiedler Lake, 377 ft (115 m) above sea level.
Population: *Estimated 2002 population*—8,255,000; density, 255 per mi² (98 per km²); distribution, 65 percent urban, 35 percent rural. *1991 census*—7,795,786.
Chief products: *Agriculture*—barley, cattle, corn, grapes, hogs, milk, potatoes, sugar beets, wheat. *Manufacturing*—cement, chemical products, electrical equipment, furniture, glass, iron and steel, leather goods, lumber, machines and tools, motor vehicles, optical instruments, paper and pulp, processed foods and beverages, textiles and clothing. *Mining*—coal, copper, graphite, iron ore, lead, magnesite, natural gas, petroleum, salt, zinc.
National anthem: "Land der Berge, Land am Strome" ("Land of Mountains, Land at the River").
Money: *Basic unit*—euro. One hundred cents equal one euro. The schilling was taken out of circulation in 2002.

Government

Austria is a federal republic made up of nine provinces: Burgenland; Carinthia; Lower Austria; Salzburg; Styria; Tyrol (or Tirol); Upper Austria; the city of Vienna; and Vorarlberg. Its Constitution was adopted in 1920. All Austrians 19 years and older may vote.

The president is Austria's head of state. The people elect the president to a six-year term. The president may serve any number of terms but no more than two in a row. The president's duties are largely ceremonial. They include appointing ambassadors and acting as commander in chief of the armed forces. But the president does not have the power to declare war or to *veto* (reject) bills passed by Parliament.

The chancellor and Cabinet run the Austrian government. The *chancellor* (prime minister) serves as head of government. Generally, the president appoints as chancellor the leader of the political party with the most seats in the *Nationalrat* (National Council). The Nationalrat is the more important of the two houses of the Austrian Parliament. On the chancellor's advice, the president also appoints members of the Cabinet to head the government departments. The chancellor and Cabinet form government policies and are responsible to the Nationalrat. The Nationalrat may force the chancellor and Cabinet to resign by rejecting their policies in a *vote of no confidence.*

The Parliament. The Nationalrat forms the lower house of Austria's Parliament. The upper house is called the *Bundesrat* (Federal Council). The Nationalrat has 183 members, elected by the people to four-year terms. But the Nationalrat may dissolve itself at any time, or the president may dissolve it on the chancellor's advice. New elections then take place. The Bundesrat's 63 members are elected by the country's nine *Landtags* (provincial legislatures). Members of the Bundesrat serve as long as the Landtag that chose them stays in power. The number of members a province has in the Bundesrat varies according to population.

Provincial and local government. The people in each province elect Landtag members to four- to six-year terms, depending on the province. Each Landtag chooses the governor of the province. The provinces are subdivided into about 2,320 *communes* (units of local government). Voters in each commune elect a governing council, which selects one of its number to serve as mayor. Vienna is both a province and a commune. Its communal council serves as the provincial legislature, and its mayor serves as governor.

Political parties. Three political parties control the great majority of seats in the Nationalrat. They are the liberal Social Democratic Party, the conservative People's Party, and the far-right Freedom Party. Other parties include the Greens and the Liberal Forum.

Courts. The Supreme Court is Austria's highest court of appeal in civil and criminal cases. Four regional courts hear appeals of decisions made by lower courts. Various special courts handle juvenile matters, labor disputes, and administrative and constitutional cases.

Armed forces. Austria has about 55,000 men in its armed forces. Men 18 years of age must serve at least six months in the army with additional periods of follow-up training later.

Austrian Tourist Board

Parliament Building in Vienna is the meeting place of both houses of the Austrian legislature. The building, designed in the Greek classical style, dates from the late 1800's.

Austria's flag has stripes of red, white, and red. It is one of the oldest national flags, dating from the 1200's.

Coat of arms was adopted in its present form in 1945. The use of an eagle to symbolize Austria dates from the 1100's.

WORLD BOOK map

Austria is a landlocked country in central Europe. It is surrounded by eight other European countries.

Austria is divided into nine provinces.

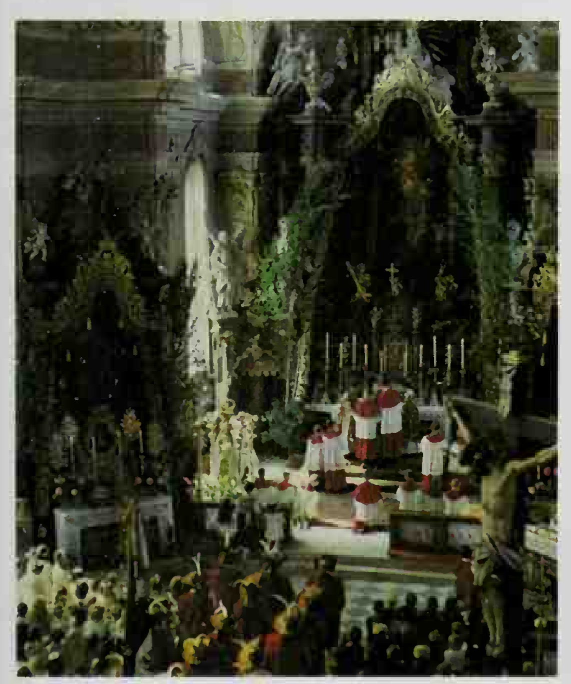
*Does not appear on map; key shows general location.
Source: 1991 census.

Most of Austria's people live in the lower areas of the country—in the east and just south of the Danube River. About a fifth of the people live in Vienna, the country's capital and largest city.

Ancestry. Many different groups of people have settled in Austria. Each group mixed with other peoples and so helped shape the ancestry of present-day Austrians. In ancient times, the peoples of Austria included Celts and Romans. Later, Asians, various Germanic groups, and *Magyars* (Hungarians) settled in Austria. From the 1300's on, Austria attracted peoples from many parts of central Europe. These peoples included Italians and various Slavic groups. During the 1950's and 1960's, many people fled to Austria from Communist-controlled Czechoslovakia and Hungary.

As a result of this mixing of peoples, there is no "typical" Austrian. Some are tall and slim, with fair skin, blue eyes, and blond hair. Others are short and stocky, with fairly dark skin, brown eyes, and brown hair. Many others do not fit either description.



Language. Almost all Austrians speak German, the country's official language. In different parts of the country, the people speak various *dialects* (local forms) of German.

A number of Austrians speak another language as their first language. In the province of Burgenland, for example, there are communities of people who speak Serbo-Croatian. Burgenland also has some people who speak Magyar. Carinthia has a number of people who speak Slovenian. Small groups of people in Vienna speak either Czech or Slovak.

Way of life. Most city dwellers in Austria live in four- or five-story apartment buildings. Others live in high-rise apartment buildings or in one-family homes. Many farm and village families live in single-family homes. The style of these houses varies from region to region. For example, many homes in Burgenland are simple in design and covered with a kind of plaster called *stucco.* The provinces of Tyrol and Vorarlberg have many wooden *chalets* similar to those of Switzerland. Most chalets have a steep, pointed roof that hangs out over the sides of the house.

Austrians wear clothing much like that worn in the United States, but they dress up somewhat more than Americans do. On special occasions, many Austrians wear traditional national or regional costumes. Men may wear a green-trimmed, gray wool suit consisting of a coat and *knickers*—short, loose-fitting trousers gathered in just below the knee. Women may wear a peasant costume called a *dirndl.* It consists of a blouse; a wide girdle worn over the blouse and laced up the front; and a full, brightly colored skirt and apron.

Austrians appreciate good food. Many of their dishes have been influenced by Czech, German, or Hungarian cooking. Popular meats in Austria include beef, chicken, pork, sausage, and veal. An Austrian dish called *Wiener schnitzel* (breaded veal cutlet) has become a favorite in many countries. Popular side dishes in Austria include dumplings, noodles, and potatoes. The people drink beer or wine with many meals. The delicious cakes and pastries created by Austrian bakers have become world famous.

H. Gritscher. Black Star

Austrians attend Mass at a Roman Catholic church designed in the highly decorated *rococo* style of the 1700's. Most of the Austrian people belong to the Catholic Church.

Francis O. Spalding. Tom Stack & Associates

Charming old Vienna, Austria's capital and largest city, has many sidewalk cafes and beautiful buildings. The monument above was built in memory of a plague that hit Vienna in 1679.

Festivals and holidays play an important part in Austrian life. Some festivals date from pre-Christian times. One such festival takes place throughout the Tyrol at the beginning of spring, when the people pretend to chase away the "evil spirits" of winter. Wearing special costumes and masks, they march through the streets and wave large sticks in the air. The name and date of this festival vary from place to place.

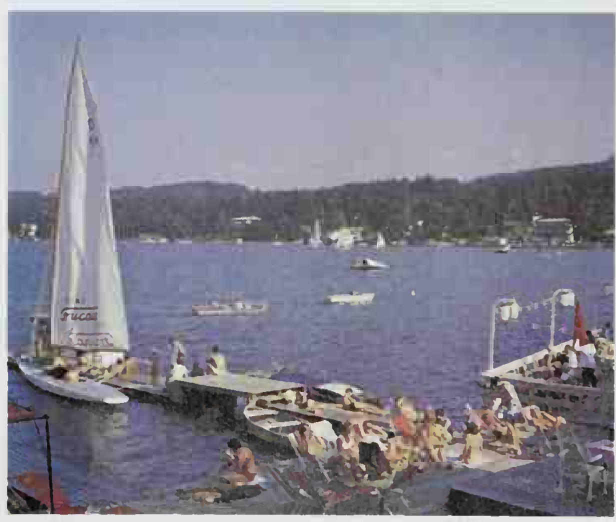
Social welfare. The Austrian government provides a number of welfare services. Under the national social insurance program, workers may receive disability, maternity, old-age, sickness, survivors', or unemployment benefits. Austria also has a national health insurance program for all citizens. The costs of both programs are shared by insured people; employers; and the federal, provincial, and local governments.

Since 1919, Austrian law has limited the workday to eight hours and has guaranteed employed people annual holidays. Today, employed people who have been on the job for six months or longer receive at least an 18-day vacation with pay each year. In 1975, the workweek became limited to 40 hours.

Recreation. Austrians love the outdoors, and their country's many forests, lakes, and mountains offer opportunities for a variety of outdoor sports. In winter, the people especially enjoy ice skating, skiing, and tobogganing. Other popular winter sports include bobsledding; ice hockey; ski jumping; and *curling,* a game in which the players slide heavy stones along the ice toward a circular target. Favorite summer sports include boating, fishing, hiking, mountain climbing, swimming, and water skiing. The people also enjoy bicycling, camping, picnicking, and playing soccer.

Austrians love the arts as well as sports. Ballets, concerts, motion pictures, operas and operettas, and plays all attract large, enthusiastic crowds.

Education. Almost all adult Austrians can read and write. For the country's literacy rate, see **Literacy** (table: Literacy rates for selected countries). Austrian children between the ages of 6 and 15 are required to attend school. Most students attend free public schools. The rest attend private schools, which may charge a tuition fee.



Austrian students may choose from a variety of educational programs. The minimum program requires a student to attend eight years of elementary school and one year of either vocational school or *polytechnical school,* which offers courses in the arts and sciences. Students who wish to go to a university may attend (1) elementary school for four years and high school for nine years; (2) elementary school for eight years, preparatory school for one year, and high school for four years; or (3) elementary school for eight years and vocational high school for five years.

Austria has 12 universities and 6 fine arts colleges. The University of Vienna is the country's largest university.

Religion. Austria and the pope have a *concordat* (agreement) under which the Roman Catholic Church in Austria receives financial support from the national government. But Austrians have freedom of worship. About 80 percent of the people are Roman Catholics, and about 5 percent are Protestants. Austria also has about 12,000 Jews, most of whom live in Vienna.

The arts. Austria has long been one of the great cultural centers of Europe. The country has made outstanding achievements in architecture, literature, and painting. But its most famous and important contributions to Western culture have been in music.

Music. Austria has produced many great composers. During the late 1700's and early 1800's, Joseph Haydn helped make the symphony one of the most important

Boating and other water sports are enjoyed by both Austrians and tourists during the summer. The country has many popular summer resort areas, including Lake Wörther, *above,* in the province of Carinthia.

H. Gritscher, Black Star

A centuries-old festival takes place in the Tyrol at the start of spring. In this festival, people in costumes and masks use sticks to chase away winter's "evil spirits."

The Vienna State Opera House presents operas almost every day for 10 months of the year. Music and drama are popular in Austria, and operas attract large, enthusiastic crowds.

John Launois, Black Star

Austrian bakers create some of the delicious pastries for which their country is famous. Coffee and pastry make up a favorite snack among Austrians.

forms of musical composition. Haydn and Wolfgang Amadeus Mozart became the leading composers of the *classical period* of music. Mozart wrote masterpieces in a wide range of musical forms. Many people consider his *Don Giovanni* the world's greatest opera.

During the early 1800's, Franz Schubert composed more than 600 songs. His "Ave Maria" and "Who Is Sylvia?" are among the most beautiful songs ever written. Gustav Mahler and Hugo Wolf, who wrote in the late 1800's, rank with Schubert as composers of songs. Anton Bruckner wrote emotionally powerful symphonies during the middle and late 1800's. Also during the 1800's, Johann Strauss and his son, Johann Strauss, Jr., composed their famous waltzes.

Arnold Schoenberg became one of the most revolutionary composers of the 1900's. He developed a new system of composition called the *twelve-tone technique.* Schoenberg influenced many composers, including his fellow Austrians Alban Berg and Anton Webern.

Austria today continues to make important musical contributions. The Vienna Boys' Choir, Vienna Philharmonic, Vienna State Opera, and Vienna Symphony Orchestra have won international fame. The annual Salzburg Festival is one of the great musical events of the year. Students from all over the world study at Austria's fine music schools.

Architecture. Austria has some of Europe's best examples of *baroque* architecture. This highly decorated style dates from the 1600's. Through the use of such materials as gold, marble, and wood, baroque architects created buildings that pleased the senses. At the same time, their buildings appealed to people's spiritual nature because they were decorated with paintings and sculptures of religious and mythical figures. Johann Bernhard Fischer von Erlach was one of Austria's leading baroque architects. His designs include the Karlskirche (Church of St. Charles) in Vienna and the Church of the Holy Trinity in Salzburg.

Austria also has many churches, palaces, and other buildings designed in the *rococo* style of the 1700's. Rococo architecture is even more decorated than baroque.

During the late 1800's and early 1900's, Adolf Loos developed a simplified style of architecture marked by uncluttered lines and flat surfaces. His work did not become highly popular in Austria. But it strongly influenced architects in the United States.

Literature. Austrians have a deep love for the theater, and many of the country's most important writers have been playwrights. One of the most outstanding was Franz Grillparzer, who wrote in the early 1800's. Grillparzer's plays drew on the traditions of classical German drama as well as on the humor and liveliness of Austrian folk drama.

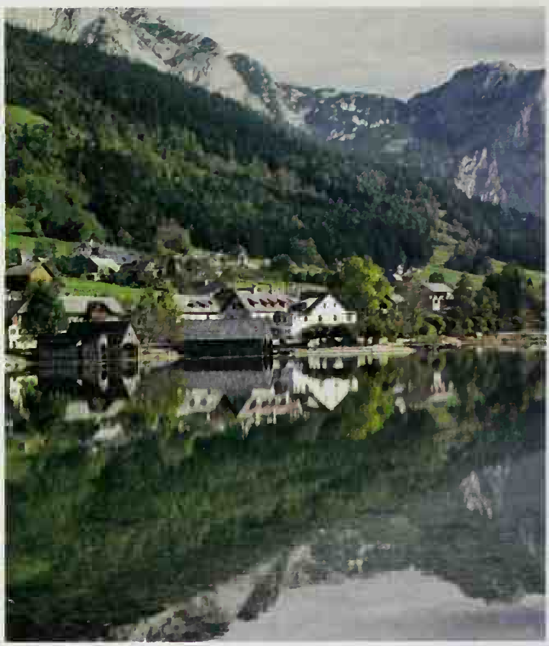
During the late 1800's and early 1900's, Arthur Schnitzler became famous for exploring the psychology of human emotions in his plays and stories. Hugo von Hofmannsthal, a playwright and poet of the early 1900's, shared Schnitzler's interest in psychology. Other important Austrian writers of the 1900's included Franz Werfel and Stefan Zweig.

Painting. Gustav Klimt, who worked in the late 1800's and early 1900's, was one of Austria's first painters of international importance. In his works, Klimt explored the inner nature of human beings and tried to express his own strong emotions. Two of Klimt's followers—Egon Schiele and Oskar Kokoschka—carried his ideas still further. Their paintings reflected an art movement of the early 1900's called *expressionism.*

The land and climate

Mountains cover about three-fourths of Austria. The Alps stretch across the western, southern, and central parts of the country. A separate mountainous area, the *Granite Plateau,* lies in the north. The country's highest point, the mountain Grossglockner, stands 12,457 feet (3,797 meters) above sea level in central Austria.

The Danube, the country's longest river, flows 217 miles (350 kilometers) from west to east through northern Austria. Almost all Austrian rivers flow into the Danube. Austria's largest lake is Neusiedler Lake. Part of this lake lies in Hungary. The Austrian part covers 51 square miles (132 square kilometers).



Land regions. Austria has six main land regions. They are (1) the Granite Plateau; (2) the Eastern Forelands; (3) the Alpine Forelands; (4) the Northern Limestone Alps; (5) the Central Alps; and (6) the Southern Limestone Alps.

The Granite Plateau forms Austria's northernmost region. It consists of hills and mountains that are made up mostly of granite and partly covered by thick forests.

The Eastern Forelands lie southeast of the Granite Plateau. The northern part is a lowland called the Vienna Basin. Its fertile soil helps make it Austria's chief agricultural area. The southern part consists of rolling hills and broad valleys, with the land becoming flatter in the east.

The Alpine Forelands lie south of the Granite Plateau and west of the Eastern Forelands. The region is made up of hills and low mountains.

The Northern Limestone Alps rise south and southwest of the Alpine Forelands. The mountains in this re-

gion consist of limestone. The region is marked by high plateaus; steep, forested slopes; and jagged peaks. Several large lakes formed by ancient glaciers are found in this region.

The Central Alps are separated from the Northern Limestone Alps to the north by a series of valleys. Unlike the Northern Limestone Alps, the Central Alps do not consist of limestone but of such rock materials as granite and gneiss. The Central Alps have Austria's highest mountains. Large glaciers cover many of the mountain peaks.

The Southern Limestone Alps lie south of the Central Alps. A series of valleys separates the two regions. The physical features of the Southern Limestone Alps resemble those of the Northern Limestone Alps.

Climate. Austria has four sharply defined seasons. The country's climate is influenced by both west and east winds. Warm, moist winds blowing eastward from the Atlantic Ocean affect the climate of western and central Austria. These winds bring *precipitation* (rain, snow, and other forms of moisture) and help produce moderate temperatures the year around. Dry winds blowing westward from the Asian plains are hot in summer and cold in winter. Partly as a result of these winds, eastern Austria has less precipitation and more extreme temperatures than western and central Austria.

Within the western, central, and eastern areas, Austria's climate varies from place to place, partly because of differences in altitude. Local winds also influence the climate. For example, warm, dry winds called *foehns* cause sudden rises in temperature in some mountain valleys in winter. Because they may rapidly melt mountain snow, foehns sometimes cause destructive avalanches (see Foehn).

January temperatures in Austria average about 27 °F (−3 °C). July temperatures average about 67 °F (19 °C). The country receives an average of about 25 inches (64 centimeters) of precipitation yearly.

Economy

Austria's economy is based mostly on private ownership. But the government owns companies in several industries as well as certain transportation and communication services. The country's economy was brought to a standstill as a result of World War II (1939-1945). In the late 1940's, the Austrian government purchased most of the companies in certain industries. These industries included coal and metal mining; electric power production; iron and steel production; and oil drilling and refining. Large amounts of aid from the United States helped the government rebuild these industries.

Since the early 1950's, Austria has become increasingly industrialized, and its economy has grown steadily. Today, Austria is a prosperous country with little unemployment.

Natural resources. Austria has a variety of minerals. But most deposits are too small to meet the country's needs, or the quality is low. For example, Austria's coal—found chiefly in Styria—consists almost entirely of *lignite,* a low-quality brown coal. Austria must thus import high-quality coal. The Erzberg (Ore Mountain) in Styria has much iron ore. But the country has to import some high-grade iron ores. Petroleum and natural gas must also be imported because the country's reserves, found mostly in Lower Austria, do not meet its needs.

Austria ranks as one of the world's leading producers of magnesite, which is used to make such products as heat-resistant bricks, plaster, and artificial stone. The country is also a leading producer of graphite, which comes mostly from Lower Austria. Other mineral deposits include copper, lead, salt, and zinc.

Austria's rich forests, which cover about 40 percent of the country, provide plentiful lumber, paper, and other products. Spruce and fir are the most commercially important trees. Strict conservation laws and extensive replanting programs prevent the forests from being used up.

Austria's swift-flowing rivers are perhaps its most important natural resource. They provide energy for many hydroelectric power stations, which produce most of the nation's electric power.

Service industries, taken together, account for the largest part of Austria's *gross domestic product* (GDP)—the total value of goods and services produced within a country in a year. Community, government, and personal services form one of the most important service industries in terms of the GDP and employ about a fourth of the workers. The government controls several of Austria's major companies. Community, government, and personal services also include the operation of schools and hospitals. Foreign investment in Austria's banks helps to make finance, insurance, real estate, and business services another important service industry. Trade,

Austrian Tourist Board

The production of fine handicrafts forms an important part of Austria's economy. Craftworkers make a variety of objects, including glassware, *shown here,* jewelry, and woodcarvings.

Skiers from many countries flock to the superb ski areas in the Austrian Alps every winter. The booming tourist industry adds more than $1 billion to Austria's annual national income.

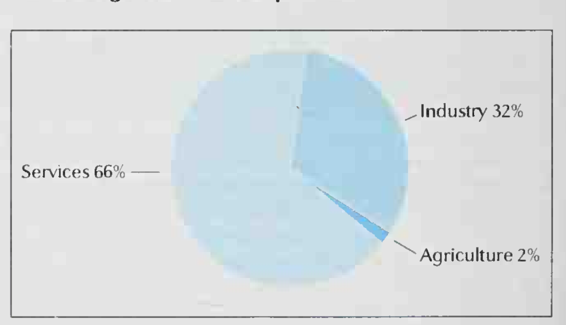
restaurants, and hotels benefit from heavy spending by tourists. The other service industries include transportation and communication.

Manufacturing. Austria's leading manufacturing activities are the production of metals and metal products. The chief metals include iron and steel. The main metal products include automobiles and other motor vehicles, locomotives, machines and tools, and ships. Other major manufactured products are chemical products, electrical equipment, processed foods and beverages, and textiles and clothing. Austrian factories also produce cement, furniture, glass and porcelain products, lumber, optical instruments, and paper and pulp.

Factories are scattered throughout Austria, but the heaviest concentration is in the Vienna area. Manufacturers tend to stress high quality rather than mass production. Many factories are small or medium-sized. In small workshops throughout Austria, skilled craftsmen produce excellent glassware, jewelry, needlework, porcelain objects, woodcarvings, and other handicrafts.

Agriculture. Austria is so mountainous that only about 20 percent of the land can be used for growing crops. But the country's farmers use modern machinery and scientific farming methods. As a result, they can supply more than three-fourths of the food needed by the people. All Austrian farms are privately owned. Since the late 1940's, there has been a trend toward larger farms. But most farms in Austria are still small.

Dairy farming and livestock production are the main sources of farm income. Austria's farmers produce all the eggs, meat, and milk needed by the people. Farm animals graze in the high areas of the country, where it is too rugged and cold for growing crops.



The best croplands are in the Vienna Basin. But farm plots can be found in every province. The farmers produce all the potatoes and sugar beets and most of the barley, oats, rye, and wheat needed in Austria. Other farm crops grown in the country include apples, corn, grapes, hay, hops, and vegetables.

Tourism. Austria is one of Europe's most popular vacationlands. Millions of tourists visit the country every year. The booming tourist industry adds more than $1 billion to Austria's annual national income.

Innsbruck, Kitzbühel, and other sports centers in the Alps attract many winter vacationers, especially skiers. In summer, the lakes of Carinthia and of the Salzkammergut area in central Austria are popular recreation spots. Vienna's art galleries, concert halls, and museums also attract many tourists, as do the summer music festivals held throughout the country.

Foreign trade. Austria depends heavily on trade, especially trade of manufactured goods with other European industrialized nations. It imports some types of machinery and vehicles and exports other types. The country's other imports include foods and petroleum.

Austria's gross domestic product

Austria's gross domestic product was $208,182,000,000 in 1999. The gross domestic product is the total value of goods and services produced within a country in a year. *Services* include community, government, and personal services; finance, insurance, real estate, and business services; trade, restaurants, and hotels; and transportation and communication. *Industry* includes construction, manufacturing, mining, and utilities. *Agriculture* includes agriculture, forestry, and fishing.

Production and workers by economic activities

Economic activities	Percent of GDP produced	Employed workers: Number of people	Employed workers: Percent of total
Finance, insurance, real estate, & business services	22	382,400	10
Community, government, & personal services	20	947,900	25
Manufacturing	20	763,300	20

Other exports include forest products, including paper and pulp; iron and steel; and magnesite. The value of Austria's imports is greater than that of its exports. Income from tourism largely makes up the difference.

Austria's chief trading partner is Germany. Both countries are members of the European Union (EU). The EU is an organization of European nations that works for economic and political cooperation among its member nations. Most of Austria's trade is with EU members or with members of the European Free Trade Association (EFTA), an economic organization of European nations. EU and EFTA members have removed almost all tariffs and other restrictions on imports of manufactured goods from one another. See **European Free Trade Association; European Union** (History).

Transportation. Austria has an excellent road network. Almost all Austrian families own an automobile. Railroads link almost all cities and towns. The federal government owns 90 per cent of the nation's railroad tracks. Both buses and trains provide fast and frequent passenger service. Many mountain areas have cable railways.

The federal and provincial governments own most of the stock in the national airline, Austrian Airlines. The airline operates international and domestic flights. Foreign airlines also serve the country. Vienna has Austria's chief airport. The Danube River is a major shipping route for trade between Austria and nearby countries. Passenger vessels also travel on the Danube.

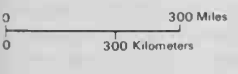
Communication. Austria has about 30 daily newspapers. The federal and provincial governments own the nation's radio and television network. People who own a radio or television set pay a monthly fee for its use. The federal government operates the postal, telegraph, and telephone services. Most families in Austria have a radio, television set, and telephone.

History

Early years. People have lived in what is now Austria for thousands of years, but historians do not know much about the earliest inhabitants. They do know that after about 800 B.C., the people mined and traded iron ore and salt. About 400 B.C., a people called Celts began to move into central and eastern Austria.

By 15 B.C., the Romans controlled Austria south of the Danube, and they made it part of their empire. In the late A.D. 100's, warlike tribes from the north began to invade Roman Austria, and Roman control slowly weakened. In 476, the Roman Empire collapsed. During the period of the empire's decline, groups of Asians, Germans, and Slavs invaded and settled in Austria.

In the late 700's, Austria came under the rule of Charlemagne, king of a Germanic people called the Franks. After Charlemagne's death in 814, the Frankish empire gradually broke up. In the 900's, tribes of Magyars overran Austria. But the king of Germany, Otto I, defeated them in 955. Austria then came under his rule. In 962, the pope crowned Otto emperor of what later became known as the Holy Roman Empire. German emperors ruled the Holy Roman Empire until it ended in 1806. Austria became the empire's most important state.



In 976, Emperor Otto II gave control of northeastern Austria to Leopold I of the Babenberg family. In 1156, Emperor Frederick I increased the importance of this area by declaring it a *duchy*—a territory ruled by a duke. In 1186, the Duchy of Styria, which lay south of the Duchy of Austria, also came under Babenberg rule.

The Habsburgs. The last Babenberg duke died without an heir in 1246. King Ottokar of Bohemia then gained control of the Babenberg duchies of Austria and Styria, plus some lands to the south. In 1273, the princes of Germany elected Rudolf I, a member of the Habsburg family of Switzerland, as Holy Roman emperor. Rudolf defeated Ottokar in battle in 1278 and began to acquire for his family the lands that the king had taken.

In the 1300's, the Habsburgs lost the Holy Roman crown. The empire was a disorganized patchwork of states ruled by various families, including the Habsburgs. In 1359, the great-grandson of Rudolf I, Rudolf IV, claimed the title of archduke of Austria. But his claim was not recognized by other European rulers until 1453. In that year, the Duchy of Austria became the Archduchy of Austria. In time, the Habsburgs acquired the other regions that make up present-day Austria.

The Habsburg lands

In 1282, almost all of what is now Austria, outlined in red, formed part of the Holy Roman Empire. The Habsburg family controlled the areas shown in yellow. In 1526, the Habsburg lands included Bohemia, part of Hungary, and other areas.

WORLD BOOK maps

Austria-Hungary in 1914

Austria-Hungary, established in 1867, consisted of the Austrian Empire and the Kingdom of Hungary. Austria-Hungary had reached its greatest size in 1914, when World War I began. It broke up at the end of the war in 1918.

WORLD BOOK map

In 1438, a Habsburg had again been elected Holy Roman emperor. From then on, the Habsburgs held the title almost continuously. Their Archduchy of Austria became the empire's chief state. One of the greatest Habsburgs was Maximilian I. In 1496, he arranged for his son, Philip, to marry the daughter of the king and queen of Spain. Philip's son became King Charles I of Spain in 1516 and Holy Roman Emperor Charles V in 1519. In 1556, Charles gave up the two thrones. Spain went to his son, and Austria and the title Holy Roman emperor went to his brother, Ferdinand I. The Habsburgs thus became divided into Spanish and Austrian branches.

Ferdinand had become king of Bohemia and Hungary in 1526. He fought against the Ottoman Empire, which had conquered a large part of Hungary. The Ottomans attacked Vienna twice but failed to capture it. They were driven out of almost all of Hungary in the late 1600's.

In 1618, Protestants in Bohemia revolted against their Habsburg ruler, who was a Roman Catholic. But they were defeated in 1620. The revolt became the start of the Thirty Years' War (1618-1648). This series of religious and political wars eventually involved most European nations. The Peace of Westphalia, which ended the Thirty Years' War, declared that each German ruler could determine the official religion of the state. The Habsburgs could thus force Catholicism on the people in their lands.

Wars in the 1700's and 1800's. The last Habsburg king of Spain died in 1700. Both Austria and France claimed the throne. The War of the Spanish Succession (1701-1714) followed. Austria won Belgium and Spain's Italian lands. A French prince became king of Spain.

Charles VI, archduke of Austria, became Holy Roman emperor in 1711. He had three daughters but no sons. An old European rule known as the *Salic law* prohibited a woman from inheriting a kingdom (see Salic law). But in 1724, Charles publicly announced a decree called the *Pragmatic Sanction.* This decree made his oldest daughter, Maria Theresa, heir to the Habsburg possessions. The principal European states agreed to recognize the Pragmatic Sanction.

After Charles VI died in 1740, several states broke their promise and challenged Maria Theresa's right to rule. They tried to take her lands in the War of the Austrian Succession (1740-1748). In the war, Maria Theresa lost one of her lands, Silesia, to Prussia. But the powers of Europe recognized her as ruler of Austria, Bohemia, and Hungary. In the Seven Years' War (1756-1763), she tried unsuccessfully to regain Silesia.

Austria suffered many defeats in the Napoleonic Wars of the late 1700's and early 1800's. In these wars, Napoleon I of France fought an alliance of European states that included—in addition to Austria—Britain, Prussia, and Russia. Napoleon conquered large parts of the Holy Roman Empire, and in 1806 he forced Emperor Francis II to dissolve the empire. In 1804, Francis had changed his title from archduke to emperor of Austria. After 1806, he reigned as Emperor Francis I of Austria. Napoleon was finally defeated in 1815.

Metternich and revolution. The major political figure in Austria from 1809 to 1848 was Prince Klemens von Metternich, who served as minister of foreign affairs. Metternich played a leading role at the Congress of Vienna. The congress was a series of meetings of European political leaders that arranged the peace settlement following the Napoleonic Wars. The congress returned to Austria most of the land it had lost. But Austria gave up its claim to Belgium. The congress also set up the German Confederation, a loose union of independent states. Austria and Prussia began a struggle to lead the confederation.

During the 1800's, the forces of democracy and nationalism swept across Europe. Revolutions broke out in many areas. Because he feared revolution, Metternich tried to put down all democratic or nationalist movements in the Austrian Empire. But in 1848, revolution began in France and spread to Bohemia, Hungary, and even Vienna. In Vienna, revolutionaries demanded that Metternich resign and that a constitutional government be set up. Metternich fled to England. Revolts also broke out in the Austrian-controlled states in Italy. But by 1851, the Austrian army had put down all revolts.

Important dates in Austria

15 B.C. The Romans controlled Austria south of the Danube River.

A.D. 100's Warlike tribes from the north began to invade Roman Austria, and Roman control started to weaken.

476 The Roman Empire collapsed.

976 The Holy Roman emperor gave control of northeastern Austria to Leopold I of the Babenberg family.

1278 Rudolf I, a Habsburg, began to acquire the Babenberg territory and nearby lands for his family.

1438-1806 The Archduchy of Austria was the most important state in the Holy Roman Empire.

1867 Austria-Hungary was established.

1914-1918 Austria-Hungary was defeated in World War I.

1918 The Habsburgs were overthrown, and Austria became a republic.

1938 Adolf Hitler made Austria part of Germany.

1939-1945 The Allies defeated Germany in World War II.

1945-1955 Britain, France, the Soviet Union, and the United States occupied Austria.

1995 Austria joined the European Union, an economic and political organization of European nations.

In the following years, *unification movements* in Italy and Germany weakened the empire. In the various Italian states, many people wanted national unity under the king of Sardinia. Austria declared war on Sardinia in 1859. Italian and French forces defeated the Austrians. As a result of the defeat, Austria gave up its Italian state of Lombardy and lost its influence in other Italian states. In Germany, Prussia sought to unite the northern states under itself. In 1866, a minor dispute led to the Seven Weeks' War, in which Italy and Prussia quickly defeated Austria. The German Confederation was dissolved. Prussia formed a new confederation without Austria.

Austria-Hungary. In 1867, the Hungarians forced Emperor Francis Joseph to give Hungary equal status with Austria by setting up the *Dual Monarchy* of Austria-Hungary. Under this arrangement, both the Austrian Empire and the Kingdom of Hungary pledged allegiance to Francis Joseph. The two countries also were united in their conduct of foreign, military, and certain financial affairs. But each country had its own constitutional government to handle all other matters.

In the late 1800's and early 1900's, Slavs and other minority groups in Austria-Hungary demanded the right to govern themselves. Serbia, a Slavic country south of Hungary, led the Slavic nationalist movement. In 1914, Gavrilo Princip, a Serbian from Bosnia-Herzegovina, killed Archduke Francis Ferdinand, heir to the Austro-Hungarian throne. Austria-Hungary then declared war on Serbia, marking the start of World War I (1914-1918). Germany and other nations joined Austria-Hungary in fighting the Allies, which included Britain, France, Russia, and the United States.

After World War I. A defeated Austria-Hungary signed an armistice on Nov. 3, 1918. On November 12, the last Habsburg emperor was overthrown, and Austria became a republic. Many Austrians wanted to make Austria part of Germany. But the Treaty of St.-Germain, signed by Austria and the Allies in 1919, forbade such a union. The treaty also established Austria's present boundaries. In 1920, Austria adopted a democratic constitution.

Austria had many political problems after the war. These problems centered on conflict between the two major parties—the Christian Social Party and the Social Democratic Party. Each party supported a private army. These armies often clashed with each other and with a group led by the Austrian Nazi Party. This party sought to unite Austria and Germany.

In March 1933, Chancellor Engelbert Dollfuss, a Christian Socialist, adjourned Parliament. This and other actions brought about a four-day war between his supporters and the Social Democrats in February 1934. The Christian Socialists won the war, and Dollfuss then ruled Austria as a dictator. Dollfuss strongly opposed the Nazi Party's goal of uniting Austria and Germany, and so, in July 1934, the Nazis killed him. Dollfuss was succeeded by Kurt von Schuschnigg. Schuschnigg also tried to keep Austria an independent nation.

In 1938, German troops seized Austria. Adolf Hitler, the German dictator, then announced the *Anschluss* (union) of Austria and Germany. Austria's fate thus became tied to that of Nazi Germany, whose quest for power led to World War II in 1939. The Allies, including Britain, France, the Soviet Union, and the United States, finally defeated Germany in 1945.

After World War II, Austria was divided into American, British, French, and Soviet zones of occupation. But the four powers allowed Austria to set up a single *provisional* (temporary) government based on the 1920 Constitution. Following elections in November 1945, a national government was formed. It included leaders of both the People's Party (formerly the Christian Social Party) and the Socialist Party (formerly the Social Demo-

Wide World

The German dictator, Adolf Hitler, *front left,* visited Vienna in April 1938. His troops had seized Austria the month before. Hitler had then announced the union of Austria and Germany, which lasted until Germany's defeat in World War II.

cratic Workers' Party). This *coalition* government helped stabilize Austria. In 1955, the Allies ended their occupation of the country. To obtain its independence, Austria agreed to be permanently *neutral*—that is, completely uninvolved in international military affairs. Later in 1955, Austria joined the United Nations (UN).

Austria had coalition governments until 1966, when the People's Party, led by Chancellor Josef Klaus, won a majority of seats in the Nationalrat. In 1970, the Socialist Party became the strongest party, though it lacked a majority. The party formed Austria's first Socialist government, with Bruno Kreisky as chancellor. In 1971, the Socialists gained a majority in the Nationalrat, and they retained their majority in the 1975 and 1979 elections.

In 1983 elections, the Socialists won the most seats in the Nationalrat but did not win a majority. They formed a coalition with the Freedom Party to keep control of the government. Kreisky resigned as chancellor following the elections. Fred Sinowatz of the Socialist Party succeeded him. The coalition broke up in 1986. In 1987, the Socialists formed a new coalition with the People's Party.

Recent developments. In 1986, Kurt Waldheim was elected to the largely honorary post of president. His campaign was marked by controversy when records surfaced concerning his possible involvement in Nazi atrocities in World War II. Waldheim denied involvement. He served as president until 1992. The day after Waldheim's election, Sinowatz resigned as chancellor. Franz Vranitzky of the Socialist Party succeeded him. In 1990 elections, the coalition of the Socialist and People's parties retained its majority. In 1991, the Socialist Party changed its name to the Social Democratic Party. In 1994 and 1995 elections, the coalition retained its majority. Austria joined the European Union in 1995. Chancellor Vranitzky retired in 1997. Viktor Klima, also of the Social Democratic Party, became chancellor.

Elections in 1999 gave the right-wing Freedom Party the second largest number of seats in the Nationalrat. This party was led by Jörg Haider, known for making pro-Nazi statements. The other parties could not build a large enough coalition without the Freedom Party, and early in 2000 the People's Party formed a coalition with Haider's group. Governments around the world reacted with concern, and the European Union enacted political *sanctions* (penalties) against Austria. Haider then resigned his leadership of the Freedom Party, but the coalition remained in place. The sanctions were lifted several months later.

Austria-Hungary, also called the Austro-Hungarian Monarchy and the Dual Monarchy, was a country in central Europe from 1867 until 1918. It was formed from the Austrian Empire, which included the Kingdom of Hungary. Austria had gained control of Hungary in the late 1600's. But in the mid-1800's, several military de-

feats weakened Austria's power. Hungary's demand for equal status with Austria led to the formation of Austria-Hungary. The Habsburg (also spelled Hapsburg) family, an influential line of rulers who held thrones in Europe as early as 1273, governed the country. Austria-Hungary gained control of the neighboring province of Bosnia-Herzegovina in 1878 and annexed it in 1908.

The monarchy covered about 260,000 square miles (670,000 square kilometers), an area slightly smaller than Texas. About 50 million people lived in Austria-Hungary, including 23 million Slavs, 12 million Germans, 10 million Magyars, and many smaller groups. Each group kept its own customs and language.

Austria-Hungary enjoyed a brilliant cultural life. During the late 1800's and early 1900's, such influential thinkers as the physician Sigmund Freud lived and worked in the capital city of Vienna. Composers Gustav Mahler and Arnold Schoenberg also contributed to the country's artistic achievements.

Austria-Hungary never became a strong nation. Its many different nationalities had a greater interest in gaining independence for themselves than in strengthening the monarchy. The country suffered from widespread discontent for more than 40 years.

In 1914, Gavrilo Princip, a Serbian from Bosnia-Herzegovina, killed Archduke Franz Ferdinand, the crown prince of Austria-Hungary. Franz Ferdinand was seen as a threat to the union of South Slavic people. In addition, the act was a protest of Austria-Hungary's control of Bosnia-Herzegovina. Most Serbs believed that Serbia, which lay south of Austria-Hungary, had a right to the province. The Serbs valued the region because it provided an outlet to the Adriatic Sea, which was important to their shipping industry.

The assassination caused Austria-Hungary to declare war on Serbia. Russia promised to support Serbia. Then Germany, Austria-Hungary's ally, declared war against Russia and Russia's ally, France. Germany invaded Belgium to attack France, and Britain joined the fight in support of Belgium. World War I had begun.

During the war, Austria-Hungary sent troops to Italy, Bulgaria, Romania, and Albania. But morale became low because of defeats. Thousands of soldiers deserted. Many from Austria-Hungary fought for the Allies.

After the war ended in 1918, the new states of Austria, Hungary, and Czechoslovakia were formed entirely from Austria-Hungary's territory. Other land went to Italy, Poland, Romania, and the Kingdom of the Serbs, Croats, and Slovenes (later called Yugoslavia). The breakup of Austria-Hungary marked the end of the empire of the Habsburg family. William J. McGrath

Authoritarianism, *uh THAWR uh TAIR ee uh NIHZ uhm,* is any form of government in which relatively few people run the country, and the rest of the population takes little part in decision making. Authoritarian states may prohibit, severely restrict, or manipulate elections to suit their own purposes. They may limit the powers of legislatures that represent the people, such as a parliament or congress, and restrict individual freedom. Authoritarianism includes such types of government as absolute monarchy, dictatorship, and totalitarianism.

The goals and methods of authoritarian governments vary. In a totalitarian state, for example, the leaders try to change society according to a set of doctrines. In an absolute monarchy or a dictatorship, the ruler may only be interested in gaining personal wealth and power. Some authoritarian states exercise cruel and unjust use of power, but others may not. Democratic states occasionally may adopt authoritarian methods of rule during a war or other emergency. Alexander J. Groth

Authority. See Power (Forms of power).

Autism, *AW tihz uhm,* is a serious medical disorder that appears in young children and persists throughout life. It is characterized by limited ability to communicate and interact with other people. Some symptoms may be present in infancy, but the condition becomes more noticeable as affected children reach the age when their peers are beginning to speak in phrases and participate in social play. In the United States, autism and related disorders, *Asperger syndrome* and *pervasive developmental disorder,* occur in 2 to 6 of every 1,000 births. Boys are more commonly affected than girls.

The American psychiatrist Leo Kanner first described the symptoms in the 1940's. He chose the name *autism,* from the Greek word for self, referring to the children's apparent lack of interest in other people.

Symptoms. Autism is diagnosed by a variety of symptoms that can occur in different combinations and range from mild to severe. However, diagnosis requires that all cases have symptoms from each of these three categories: 1) abnormal social interaction 2) abnormal communication 3) restricted and repetitive interests and behaviors.

Abnormal social interaction in persons with autism is reflected in such behaviors as failure to seek comfort from a parent and lack of eye contact. Children with autism may not respond when their name is called or play with other children. They do not understand the social behaviors necessary to make friends or work with teachers. This lack of social contact isolates people with the disorder from many experiences by which most people come to understand the world.

Abnormal communication. Most children with autism do not develop language as early as others, and some never develop language. Problems with communication extend to gestures and facial expression, as well as language. Affected children with fluent speech may talk endlessly about a single subject or use words in a way that is abnormally precise and literal. Others exhibit a speech pattern called *echolalia,* where they repeat what is said to them instead of giving their own response.

Restricted and repetitive interests and behaviors. Some children with autism appear to have only one interest, such as clocks, airplanes, or calendars, and spend their time pursuing that interest, excluding all others. Repetitive movements, such as hand flapping, rocking, or head banging, are common. Children may show

repetitive behaviors in other ways, such as placing toys in a line rather than playing with them. Children with autism often insist on sameness and become distressed by changes in their environment or routine.

Causes. Scientists know that autism is caused by an abnormality in the development of the brain. However, the nature of the abnormality has been difficult to describe. The symptoms are so complex that no single area of the brain can account for all of them. Even so, there is one consistent finding in the brains of people with autism. People with autism have a lower number of *Purkinje cells* (pronounced *pur KIHN jee)* compared to other people. These cells are important in coordination of movement and may also play a role in higher brain functions, such as planning and language. Scientists do not know, however, what part the reduction of Purkinje cells plays in the symptoms of autism.

Scientists know that susceptibility to autism is inherited. They have observed in families that parents, siblings, and other relatives of a child with autism often have some symptoms of the disorder. In addition, the diagnosis is more common in relatives than would be expected by chance. Researchers believe that autism likely results from the interaction of several genes.

Scientists also know that environmental factors play a role in autism and related disorders. Women exposed to *rubella,* also called *German measles,* or certain drugs during early pregnancy have an increased risk of having a child with autism.

Some people with autism have mental retardation, but autism occurs among individuals of all levels of intelligence. Children with autism and related disorders tend to have brains that are somewhat larger than normal, while children with mental retardation, alone, tend to have small brains. This suggests that the causes of the two conditions are different, even though they sometimes occur together.

Treatment. There is no cure for autism, but early detection and treatment can improve the lives of children with the disorder. *Behavioral intervention,* where the child is rewarded for progress toward more typical behavior, is often helpful. Many children respond with improvements on tests of language and intelligence. Drug therapy can reduce repetitive behavior in some patients. With treatment, some children with autism are able to take part in regular school classes. For others, the same treatments seem to have little effect. Scientists hope new treatments will become available as they learn more about the biology of autism. Patricia M. Rodier

Autobiography is a type of biography in which the author tells the story of his or her own life. Autobiographies give readers an inside view of the lives of interesting people. They also may provide eyewitness descriptions of historical events or accounts by people who helped shape such events. Some people use autobiographies to explain or justify actions in their lives. Some autobiographies are inspired by feelings of nostalgia for the author's past. Still others are written by celebrities who feel they can earn money from the public's curiosity about their lives.

The first genuine autobiography is generally considered to be the *Confessions* (about A.D. 400) by the early Christian leader Saint Augustine. The book tells of Augustine's spiritual struggles and triumphs. *The Autobiography of Benjamin Franklin* (1789) is probably the most famous American autobiography. By writing the book, Franklin wished to give his son and other young people a model they could imitate so they could succeed and be well known.

Many authors have written novels that are largely autobiographical. For example, the Irish novelist James Joyce's *Portrait of the Artist as a Young Man* (1916) closely resembles the author's early life. Some authors have written novels in the form of autobiographies. For example, the English author Jonathan Swift wrote *Gulliver's Travels* (1726) as a ship's surgeon's autobiographical account of experiences in strange lands. Marcus Klein

See also **Literature for children** (Books to read [Biographies and autobiographies]).

Autocracy, *aw TAHK ruh see,* is a form of government in which one person holds supreme power. This individual cannot be restricted, according to law, by any institution or group of citizens from doing whatever he or she wishes. However, some of these leaders have used the appearance of public accountability and elections to conceal their autocracies. The Russian government under the czars was an autocracy, extending from the mid-1500's to the early 1900's. Dictator Adolf Hitler's government in Germany from 1933 to 1945 was also a form of autocracy. Many countries have been controlled by autocrats since World War II ended in 1945. These autocrats included Idi Amin Dada of Uganda and Muammar Muhammad al-Qadhafi of Libya. See also **Dictatorship; Government.** Alexander J. Groth

Autogiro, *AW tuh JY roh,* is a type of heavier-than-air craft that is supported in the air by a rotor instead of by fixed wings, as an airplane is. Most autogiros have short, stubby wings for balance. An autogiro's rotor spins by itself as it passes through the air. The craft differs from a helicopter, whose rotor is always powered by an engine. The chief purpose of an autogiro's engine is to provide thrust to pull the vehicle through the air.

The rotor is set in motion through the use of gears

NYT Pictures

Autogiros have a helicopterlike rotor to keep them aloft and a nose propeller to pull them forward. These aircraft were flown mainly during the 1920's and 1930's. This photograph, taken in 1930, shows autogiros flying over New York City.

and a clutch connected to the engine. These gears are disconnected in flight, but the rotor blades continue to revolve. A hinge at each blade's hub makes the rotor somewhat flexible. When the airflow strikes each rotating blade, *lift* (upward pull) occurs. In addition, autogiros are designed in such a way that when airflow strikes the blades, it also causes them to be pulled forward around their hubs. This forward pull causes the blades to *autorotate* (rotate by themselves) and hold the craft aloft.

An autogiro can fly from 20 to 140 miles (32 to 225 kilometers) per hour. It cannot *hover* (stay motionless in the air) like a helicopter. But an autogiro requires an extremely short take-off run and can descend almost vertically to land in a small space.

Juan de la Cierva, a Spanish inventor, flew the first successful autogiro in 1923. Autogiros were later produced in Europe, the United States, and Japan. They were eventually replaced by helicopters, which are quicker and more maneuverable. Roger E. Bilstein

Autograph is anything handwritten. The term often refers to a person's signature. However, autographs also may be lengthy examples of writing, such as letters, documents, and manuscripts. The term *autograph* comes from the Greek words *autos,* meaning *self,* and *graphein,* meaning *to write.*

Collecting autographs. The hobby of collecting autographs is called *philography,* from a Greek word meaning *love of writing.* People collect many kinds of autographs. Some collect signatures or other handwritten materials of authors, composers, movie stars, or sports heroes. Others focus on certain events, such as the signing of the Declaration of Independence, a presidential election, or the space program. Some collectors try to acquire a complete set of autographs of the Presidents of the United States, the justices of the U.S. Supreme Court, Nobel Prize laureates, or Academy Award winners.

Collectors use a number of terms to identify different types of autographs. A letter completely handwritten and signed is called an *autographed letter signed* (A.L.S.). A letter either typed or handwritten by another person but actually signed by the subject is known as a *letter signed* (L.S.). The terms *autographed document signed* (A.D.S.) and *document signed* (D.S.) usually refer to legal items, such as bank checks or receipts.

Collectors may request autographs from celebrities either in person or by letter. They may also buy autographs at auctions or from dealers who guarantee the authenticity of the autographs they sell. Most beginning autograph collectors do not have the knowledge to determine whether an autograph is genuine. Many years of study are required to learn to verify handwriting and to become familiar with different types of paper and ink.

Inexperienced collectors also may mistake other kinds of signatures for genuine handwritten signatures. For example, some people have secretaries who sign their mail. Some individuals send out mass-produced letters or signed photographs to collectors who request their autographs. These *facsimile autographs* can be identified because they are not addressed to a specific person. Many famous people use a mechanical device called an *Autopen* to sign autographs. The machine can sign 3,000 signatures in eight hours. The only way to recognize an Autopen autograph is to compare two of them. All Autopen autographs are identical, but no two handwritten autographs are exactly alike.

The value of autographs varies widely. Some signatures sell for less than $5, while some handwritten letters sell for thousands of dollars. The value of many autographs depends on supply and demand. William Henry Harrison served as President of the United States for only one month in 1841 before he died. Therefore, the supply of his autograph as President is quite small. On the other hand, a number of well-known figures, such as Daniel Webster and Henry Wadsworth Longfellow, wrote many letters during their lifetime, and so their autographs are relatively inexpensive.

In all cases, the content of an autograph helps determine its value. For example, a letter written by astronaut Neil A. Armstrong that describes his walk on the moon is extremely valuable. A brief typed "thank you" letter signed by the astronaut would be relatively inexpensive.

Universal Autograph Collectors Club

Autographs of famous people. (1) Ludwig van Beethoven; (2) Napoleon Bonaparte; (3) Helen Keller; (4) Robert Frost; (5) Ronald Reagan; (6) Clark Gable; (7) Albert Einstein; (8) Robert E. Lee; (9) Mark Twain; (10) Douglas MacArthur; (11) George Washington Carver; (12) Abraham Lincoln; (13) Geronimo, who signed his name vertically, as shown above; (14) Sigmund Freud; (15) Alexander Graham Bell; (16) Winston Churchill; (17) Babe Ruth.

Preserving autographs. A collector may mount autographs in albums or put them between sheets of acid-free paper to help prevent them from turning yellow with age. Some collectors place autographs in transparent envelopes in a loose-leaf binder. These envelopes protect autographs from dirt and rough handling. Libraries usually place valuable autographs in manila folders. Herman Darvick

For examples of autographs, see Declaration of Independence; Emancipation Proclamation; English literature.

Automated teller machine (ATM) is a computer terminal that functions as a miniature financial institution. ATM's enable people to make a variety of banking transactions at any time. For example, a customer can use an ATM to make a bank deposit, withdraw a limited amount of cash, transfer funds between accounts, or get a cash advance on a credit card.

To use an ATM, a customer must have a special plastic card with a magnetic stripe across the back. The customer inserts the card into the ATM and uses the keyboard to enter a *personal identification number* (PIN) and tell the machine what to do. The machine reads the customer's account number from the magnetic stripe and performs the desired action. To dispense cash, an ATM uses either a vacuum pump or rubberized rollers inside the machine. These devices pick up bills from a stack, count them, and deliver them to the customer.

ATM's are located at banks, airports, stores, and many other public places. Most ATM's are connected to a computer network so that the customer can receive the same service at any machine.

Machines that could dispense cash came into use in the late 1960's. Automated teller machines were first introduced in the early 1970's. J. G. Adamson

See also Bank (picture); Smart card.

Automatic flight control system (AFCS), sometimes called an *automatic pilot* or *autopilot,* is a device that automatically steers aircraft. The device controls a craft using information provided by sensors along with a detailed set of computerized instructions. An AFCS reduces the amount of work a pilot must do, makes navigation easier, and improves fuel economy and flight safety. In addition, an AFCS can take over control of particularly difficult flight operations from a pilot. It can thus aid a pilot faced with such situations as landing in poor visibility or flying low to avoid radar detection.

How an AFCS works. An AFCS is part of the *avionics* (flight electronics) of an aircraft. The heart of a modern AFCS system is a computer with many high-speed digital processors. The processors communicate with other airplane systems and equipment, including *gyroscopes, accelerometers,* a *compass,* and an *air-data system.* The gyroscopes, accelerometers, and other equipment provide information about the vehicle's *attitude* (orientation in relation to the horizon), altitude, and velocity. A special compass provides information on the craft's *heading* (direction) relative to magnetic north. The air-data system provides data associated with the movement of the aircraft through the atmosphere.

The AFCS processors perform complex calculations using a set of *control modes.* Typical modes include those that maintain an aircraft's altitude, airspeed, heading, and designated flight path. The processors then issue control signals to various *servo* (or *servomechanism*) *units.* These units have motors and hydraulic devices that move the throttle and the craft's control surfaces—the ailerons, elevator, and rudder.

In a *fly-by-wire system,* a computer combines instructions from the pilot with those of an AFCS to improve flight safety. Such a system can, for example, prevent a pilot from endangering the aircraft by exceeding a certain airspeed or angle of descent or ascent.

Many airplanes include a device called a Global Positioning System (GPS) receiver that can contribute data to the AFCS. A GPS receiver can determine a plane's position in space by calculating its distance from 3 or more satellites in the GPS network. Each of the 24 satellites in this network continually broadcast their positions.

History. In 1912, Lawrence Sperry invented and flight-tested an automatic gyroscopic stabilizing device for airplanes using four gyroscopes. In 1932, the Sperry Gyroscope Company, founded by Lawrence's father, Elmer A. Sperry, developed an automatic pilot. This device enabled American aviator Wiley Post to make the first solo flight around the world in 1933 (see Post, Wiley).

In 1998, the Insitu Group, a developer of long-range unpiloted aircraft, together with the University of Washington, flew a pilotless plane across the Atlantic Ocean for the first time. The aircraft was directed by an AFCS using a GPS receiver for navigation. It took off from Newfoundland and landed in Scotland, crossing 2,030 miles (3,270 kilometers). Uy-Loi Ly

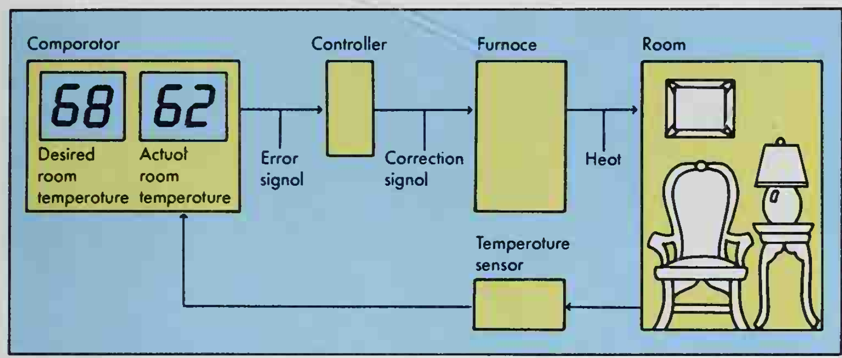
Automatic pilot. See Automatic flight control system.

Automatic transmission. See Transmission.

Automation is the use of machines to perform tasks that require decision making. Automation is used for a wide variety of jobs that are too complex or dangerous for people to do, for repetitive tasks that many people would find boring, and for work that would be extremely costly if done by people.



Uses of automation. Automated systems can make decisions that are beyond the capacity of people to make. For example, many cities use automated systems to coordinate their traffic lights to smooth the flow of traffic. Sensors in the pavement determine the number and speed of vehicles on the street and send the data to a computer. The computer decides how to time each traffic light in the area and sends signals to the lights.

Automated systems can also make decisions more quickly than people can. For example, high-speed military aircraft sometimes fly at very low altitudes to avoid detection by enemy radar. To avoid hitting obstacles, these aircraft use automated guidance systems that can react much faster than a pilot can.

Repetitive, simple jobs can be boring for people to do for long periods of time. Automated machinery is well suited to these routine tasks, such as assembling, inspecting, and packaging manufactured products.

Automated machinery can operate in environments that are unsafe for people. Automated systems are used for repairing underwater pipelines at high pressures. Automobiles are painted by robots using spray paint that would harm people.

Automated systems can do some jobs more quickly

WORLD BOOK illustration by Bill and Judie Anderson

Automated temperature control relies on *feedback.* The actual room temperature is measured by a sensor and *fed back* to a comparator that compares it with the desired temperature. Any difference between the two temperatures causes an error signal to be sent to a controller, which sends a correction signal to the furnace to adjust the heat flowing to the room.

and cheaply than people can. In many stores, checkout clerks use an *optical scanner* to read bar codes printed on product packaging. The scanner sends signals to the store's computer, which relays price and product information to the cash register. The computer records the sale, keeping a tally of how much of each item remains in stock. It can even place orders to restock items. The use of automation also allows companies to save money they otherwise would have to spend to make hazardous work areas safe for human workers. In addition, a manufacturing robot may be able to perform different tasks by having its program changed, allowing one robot to do the work of several single-task machines.

How automation works. An automated system has devices called *sensors* that pick up information about the results of the machine's operation. Sensors may also sense certain environmental conditions that affect the machine's performance. Information "read" by the sensors is fed directly back to the system, enabling the machine to adjust its operation as needed. Such a system of self-regulation is called *feedback.*

Feedback is what makes automation different from *mechanization* (the use of machinery to replace human workers or work animals). A mechanized industrial robot, for example, does not use feedback and therefore cannot adapt its operation to changing conditions.

The basic elements of feedback can be illustrated by an automated home heating system, which maintains a certain room temperature using *input* and *output.* The input is the thermostat setting—that is, the desired room temperature. The output is the actual temperature. The input tells the system what the output should be. An automated system needs sensors to measure output. The heating system's sensor is a thermometer that measures room temperature. Sensors in other systems measure such variables as pressure, size, and weight.

Automated systems compare the actual output with the desired output through devices called *comparators.* In a heating system, the thermostat acts as the comparator. It compares the thermometer reading with the temperature for which the thermostat has been set. If the actual output of the system differs from the desired output, the comparator sends an error signal to a *controller.* The controller decides how to correct the error in output. The thermostat in a heating system functions as a controller as well as a comparator. In some feedback systems, the controller may be a computer.

The part of any automated system that is controlled by feedback and changes the output is called the *process.* The controller directs the process to correct the output. In a home heating system, the process is the furnace. The thermostat turns the furnace on to raise the room temperature or shuts it off to lower the temperature.

History of automation. The first industrial application of automation was a *flyball governor,* a device that regulated the speed of a steam engine. James Watt, a Scottish engineer, constructed this device in 1787.

In the 1900's, automated controls were applied to many processes. Automated steering systems controlled by gyroscopes were first used in ships in the 1920's and came into regular use in airplanes in the 1930's (see **Automatic flight control system**).

Also at this time, the quality of telephone signals was improved by using amplifiers controlled by feedback. Automated controls used in chemical production and petroleum refining date from the early 1900's. World War II (1939-1945) further stimulated the development of automation. Automatically aimed antiaircraft guns, using radar and electronics equipment, were introduced in 1944.

The first industrial robot was used in 1961. It was controlled by a computer and worked in an automobile assembly plant. Many robots are now used in the electronics industry and in the production of automobiles, airplanes, and heavy construction machinery. Since the late 1970's, the use of computers to run machines has greatly stimulated development.

Automation and jobs. Many people expect an increase in automation to cause unemployment as workers are replaced by machines. However, while the use of automation eliminates low-skill jobs, it increases the demand for highly skilled workers. Many skilled people are needed to design, build, and maintain automated systems. In addition, automation may enable manufacturers to lower prices and increase sales. As sales increase, employment may rise. Mark A. Lawley

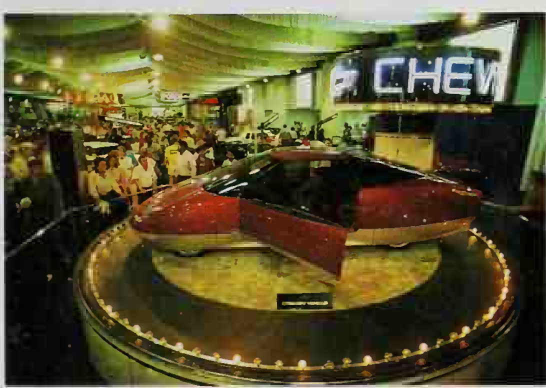
Automobile

Automobile is the most important means of personal transportation for many millions of people around the globe. People depend on their cars and trucks to travel to and from work, to run errands, to visit friends, and to take vacations. Companies and government organizations operate commercial fleets of automobiles.

The United States, Canada, Japan, Western European countries, and other developed nations have the most automobiles. But even in developing nations, more and more people own cars, and bumper-to-bumper traffic clogs the streets of big cities in many of those countries.



The origin of the automobile can be traced to Europe. But it became a major form of transportation first in the United States. Most European cars were built by hand. They were expensive, and few people could afford them. In the early 1900's, Ransom E. Olds, Henry Ford, and other pioneer automakers began mass-producing cars. Although some people disliked the "horseless carriage," many welcomed the introduction of the new machine because it would replace horse-drawn carriages. Unsightly horse droppings would no longer litter the

Auto shows let carmakers test new designs on potential buyers. The shows help continue America's "love affair with the car."

streets, creating a stench and attracting disease-bearing flies. No longer would people be burdened by the need to keep horses or be limited to traveling short distances.

The giant U.S. auto industry developed over the years as an increasing number of people bought cars. Americans were said to have a love affair with the automobile, and the United States became a nation on wheels. The automobile revolutionized the American way of life and would change living patterns in much the same way when it spread to other countries. The automobile helped give people the freedom to live, work, and travel wherever they wanted. It ended the lonely lives of farm families by placing neighbors, cities, and towns within easy reach. The automobile led to the growth of suburbs, motels, shopping centers, superhighways, theme parks, drive-in restaurants, and drive-through banks.

Interesting facts about automobiles

The word *automobile* was first applied to the horseless carriage in France about 1890. It comes from the Greek word *autos,* meaning *self,* and the French word *mobile,* meaning *moving.*
A nation on wheels. The United States has about 25 percent of the world's passenger cars. Americans drive over 2 $\frac{2}{3}$ trillion miles (4.3 trillion kilometers) a year.
Car owners. About 80 percent of all U.S. households own a car, and about 30 percent own two or more.
Vacation travel. People in the United States use their automobiles for about 80 percent of all vacation trips.
Fuel consumption by motor vehicles in the United States totals about 160 billion gallons (610 billion liters) a year—an average of about 730 gallons (2,760 liters) for each motor vehicle.
Cash and credit. About 6 percent of U.S. new-car buyers and 28 percent of used-car buyers pay cash. The rest buy on credit that totals about $470 billion a year.
Insurance premiums paid on car policies of all types in the United States total more than $135 billion a year.

Sources: American Automobile Manufacturers Association; National Automobile Dealers Association; U.S. Department of Commerce.

But along with all the glories of the automobile culture came serious problems. Car accidents became a major cause of death and injury throughout the world, exhaust fumes fouled the air, and the roar of city traffic became nerve-racking. Some people yearned for the old days before the automobile, when life seemed simpler, slower, and gentler. But there could be no going back. The automobile had become woven into the fabric of modern life. And the auto industry itself had become basic to the economic well-being of developed countries. Today, many developing nations also seek to set up an automotive industry because it generates and supports a wide range of businesses, such as automobile dealerships, garages, and filling stations, and so can stimulate economic growth.

The importance of automobiles

The development of automobiles has had an enormous effect on people's way of life throughout much of the world. Probably no other invention, discovery, or technological advance has created greater or more rapid changes in society.

Impact on society. The automobile influences where people live and work and how they spend their leisure time. It enables them to decide where they want to go and when. The striking changes in people's lives created by the automobile began in the United States and have since spread across much of the globe, especially in developed countries. But even in developing nations, the automobile is increasingly reshaping patterns of living.

When the first automobiles were produced, only the well-to-do could afford them. Soon, however, prices declined as production increased in response to the growing demand. The lower prices put the automobile within reach of more and more people. Well-off urban residents found car ownership cheaper than keeping a horse and carriage. The growth in car ownership led to the building of more and better roads, which further increased travel.

Although cars were first bought mainly by wealthy city folk, it was country people who became the first large-scale group of car owners. During the late 1890's, most people in North America and Europe lived in rural

areas and had little contact with people more than 20 miles (32 kilometers) or so away. Many of these people were farmers or residents of small towns that served farmers. In the early 1900's, they became the first mass group of car buyers. Automobiles enabled farmers to sell their goods faster and farther away, and to travel more often and in greater comfort than ever before.

Before the development of automobiles, urban workers walked, bicycled, or rode trains or horse-drawn vehicles to their jobs. But as roads improved and car ownership expanded, the freedom provided by automobile ownership enabled more and more people to move to the suburbs. By the mid-1950's, even factories had begun to relocate in the suburbs.

Wherever people have easy access to automobiles, cars play a major role in social life and the choice of recreational activities. People find it fun to hop in the car and visit friends and relatives, whether the drive takes a few minutes, hours, or days. The automobile helps make it easy to organize picnics, family reunions, and other get-togethers. Trips by automobile to such places as theme parks, national parks, and mountain and seashore resorts are a favorite type of vacation for many people.

Economic impact. Such developed nations as the United States, Japan, Germany, and Italy depend on automotive production to provide jobs for millions of workers. But even in developed nations with little or no automotive production—for example, Norway and New Zealand—the widespread use of cars has become vital to the economy. Filling stations, motels, restaurants, and other businesses that serve automobile travelers are of major importance to the economic well-being of all developed countries and increasingly of developing ones. In addition, many developing nations have begun making automotive vehicles or parts to stimulate industry and to provide the vehicles needed for growth. For example, China has promoted broad-based automotive manufacturing, and the Philippines has expanded parts production for export to carmakers in other countries. For more information on the automobile's economic impact, see the section *The automobile industry.*

Problems of safety. Each year, motor vehicle accidents kill an estimated 300,000 people throughout the world. A high percentage of those killed in automobile accidents are young people. In fact, in the United States, traffic accidents are the leading cause of death for people from 5 to 32 years old. Young people also have the highest accident rate of all drivers.

Almost every accident results from one or more of these three factors: the driver, the car, and the road. The same three factors contribute to accident prevention.

Drivers are the chief factor in vehicle safety because they are responsible for about two-thirds of all accidents. They cause accidents by speeding, driving in the

Heavy automobile traffic contributes greatly to air pollution. In the United States and many other countries, governments limit the amount of pollution new cars may produce.

wrong lane, making improper turns, and breaking other rules of safe driving. Many traffic deaths involve drunken drivers. Alcohol slows a driver's reflexes, reduces alertness and concentration, impairs vision, and clouds judgment. The use of illegal drugs by drivers is also a serious safety problem.

The automobile itself has become safer over the years because of advances in its design and manufacture. Automakers must meet strict government standards designed to prevent accidents and to protect drivers and passengers. The standards to prevent accidents involve the installation of government-specified lights, reflectors, brakes, tires, windows, windshield wipers and defrosters, and dashboard controls. Standards to protect car occupants include the installation of seat belts or air bags, head restraints, and bumper systems. Seat belts—when used—are probably the main safety equipment. A driver must not assume that the engine, brakes, lights, and steering system always operate properly. All equipment should be tested frequently.

Modern roadbuilding techniques have increasingly lowered the risk of automobile accidents. To build safe roads, highway engineers consider such factors as road foundations and surfaces, lighting, guardrails, and grading. They carefully plan bypasses, intersections, on-and-off ramps, traffic signals, and the number of lanes.

Environmental impact. As automobiles burn gasoline, they release hydrocarbons, carbon monoxide, and nitrogen oxides into the air and so pollute it. Air pollution endangers people's health and damages crops and livestock. Automobiles produce terrible pollution in many of the world's big cities. Especially severe pollution occurs in such cities as Los Angeles, Mexico City, Tokyo, and Madrid, where the streets and highways are choked with traffic.

In many countries, steps have been taken to control air pollution caused by automobiles as well as by other sources. Government agencies enforce *emission standards* that limit the amount of pollution new automobiles may produce. The agency that enforces these regulations in the United States is the Environmental Protection Agency (EPA).

Automakers have made great progress in reducing the emission of major pollutants by meeting the increasingly strict environmental standards. From the 1960's to the 1990's, the emission of hydrocarbons and carbon monoxide by American-built cars was reduced more than 95 percent and nitrogen oxides more than 90 percent. The reduction was achieved largely with the installation of a *catalytic converter* in the exhaust system of cars. The device changes carbon monoxide and hydrocarbons into carbon dioxide and water vapor. In 1990, the U.S. Congress passed new rules calling for even tougher limits on the emission of pollutants.

How an automobile works

This section describes the major interconnected systems that function together in the operation of an automobile. But first, it may be helpful to understand the basic way in which the typical car works.

Most automobiles made today have a front-mounted, gasoline-burning engine; an automatic transmission; and front-wheel drive. The typical engine is an *internal-combustion engine,* which works by burning a mixture of gasoline and air inside closed cylinders. When you turn the car's ignition key, electric current from the battery causes the starting motor to crank the engine. Pistons move up and down inside the engine's cylinders. As the pistons move down, intake valves above the cylinders open, and fuel and air are sucked into the cylinders. The pistons then move back up the cylinders, compressing the fuel-air mixture. Electric sparks from the ignition system's spark plugs ignite the mixture, and the engine starts to run as the pistons move rapidly.

Expansion of the burning gases forces the pistons down, and these downstrokes provide the power that moves the car. The pistons' downstrokes turn the crankshaft. Power travels from the crankshaft to the transmission and, finally, to the front wheels. Burned gases escape as the exhaust valves above the cylinders open and the pistons move up, forcing the waste products out through the catalytic converter, muffler, and tail pipe.

The power system. The heart of an automobile's power system—indeed, the heart of the car itself—is the engine. It produces the power that turns the wheels and that generates the electric power to operate the lights and accessories. The power system also includes (1) the fuel system, (2) the exhaust system, (3) the cooling system, and (4) the lubrication system.

The engine. Most automobiles have a gasoline engine. The majority of cars have the engine in the front of the vehicle. Others have it mounted in the rear or the middle. The *engine block,* also called the *cylinder block,* houses the engine's internal parts and provides the foundation for pumps, pulleys, and other accessory parts. Blocks are cast from iron, iron alloys, or aluminum. The engine block contains the cylinder cavities in which the pistons move.

The number and arrangement of the cylinders varies among the makes of cars. American cars have 4, 6, or 8 cylinders. Cars made in other countries also have 2, 3, 5, or even 12. In most cases, the cylinders are arranged either in a straight line or in two equal rows set at an angle to form a V shape. An *in-line engine* with, for example, 4 or 6 cylinders is called a straight 4 or a straight 6. A *V-type engine* with, for example, 4, 6, or 8 cylinders is called a V-4, V-6, or V-8. Typically, the more cylinders an engine has, the greater its power.

The gasoline engine operates on a four-stroke cycle in most cars. On the *intake stroke,* the piston moves down the cylinder and draws in a fuel-air mixture as the intake valve opens. The valve then closes, and the piston moves back up the cylinder on the *compression stroke,* squeezing the fuel-air mixture. At the top of the stroke, the spark plug ignites the compressed mixture. The burning causes the gases to expand, forcing the piston down in the *power stroke.* On the *exhaust stroke,* the piston moves up again and pushes the burned gases out the open exhaust valve. The exhaust valve then closes, the intake valve opens, and the cycle starts again.

During the power stroke, the *connecting rod* transfers energy from the piston to the crankshaft, which then transmits the energy to the transmission. For a car's wheels to turn, the up-and-down movement of the pistons must be converted to rotary motion. The connecting rod and crankshaft do the job. The connecting rod turns the pistons' up-and-down motions into the crankshaft's rotary motion.

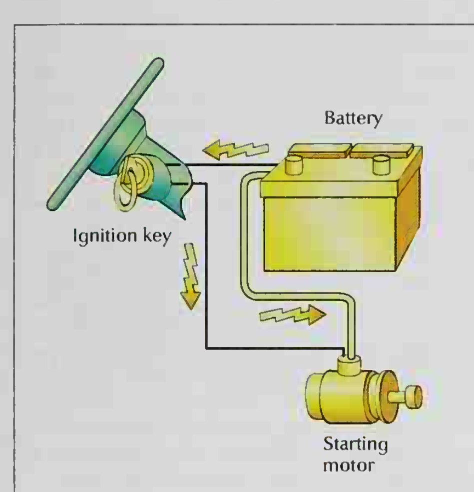
The major systems of an automobile

This diagram illustrates the major systems of a car with a front-mounted gasoline engine, an automatic transmission, and front-wheel drive. The power system produces the force that moves the car. The power train transfers power from the engine to the driving wheels. The steering and brake systems help the driver control the vehicle. The suspension system supports the car, and the electrical system produces and distributes the electric power that ignites the fuel and runs the lights, windshield wipers, and many options.

WORLD BOOK diagram by Paul Perreault

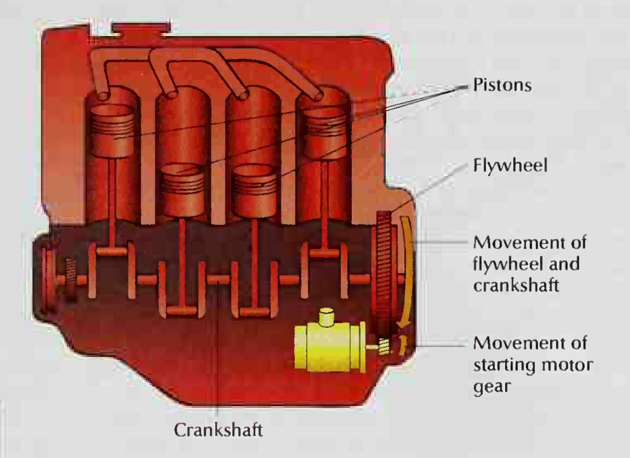
Highly advanced devices regulate modern engines. An electronic control unit receives data regarding engine speed, air pressure and temperature, and other factors. The unit uses the data to regulate the timing of the ignition sparks and the fuel flow. It adjusts the engine hundreds of times a minute.

For more information, see the article **Gasoline engine**. To learn about other types of engines used in some cars, see the articles **Diesel engine; Rotary engine; Turbine**.



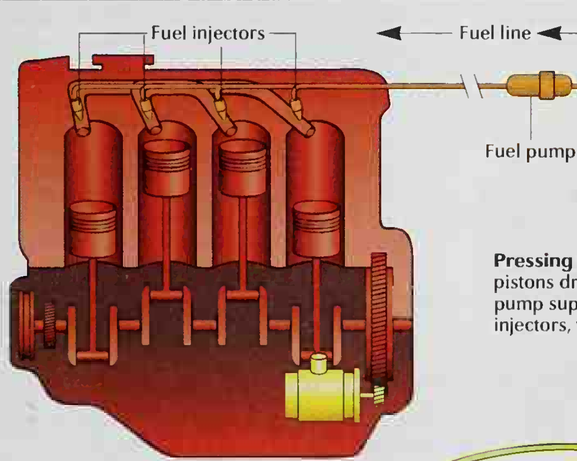
The fuel system stores fuel in a car's gasoline tank and transports it to the engine. Most tanks hold 12 to 20 gallons (45 to 76 liters) and are made of steel or plastic. The fuel system also mixes the gasoline with air. To burn efficiently, the gasoline must first be vaporized into fine droplets and then mixed with the air.

Most cars produced since the late 1980's use a system called *fuel injection,* which times and delivers precise amounts of gasoline. A pump in the fuel tank or mounted on the engine forces the gasoline under high pressure from the tank through fuel lines to fuel injectors. An injection system may be *multiport* or *single point.* Most cars today have a multiport system, also called a *direct-port system,* which has an injector for each cylinder. A single-point system, on the other hand, injects fuel into the throat of the *intake manifold,* which is basically a pipe with a branch to each cylinder. The standard injector has a needle valve. Electric current opens the



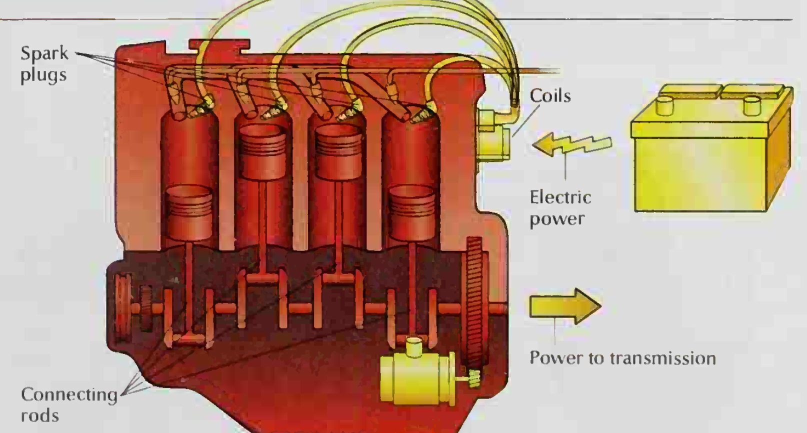
Powering the car

The typical car engine burns a mixture of gasoline and air inside closed cylinders. As the fuel burns, it produces expanding gases that force each piston down inside its cylinder. This down-stroke provides the power that ultimately moves the car. Connecting rods transmit this power to the crankshaft, which converts the pistons' up-and-down movement into rotary movement.



WORLD BOOK diagrams by Paul Perreault

Ignition begins when the key turns the starting switch. Electric power flows from the battery to the starting motor, which cranks the engine.



Cranking takes place as the starting motor spins the flywheel. The flywheel turns the crankshaft, which starts the pistons moving up and down in the cylinders and activates the fuel pump.

Pressing the accelerator opens the throttle, letting the pistons draw the fuel mixture into the cylinders. The fuel pump supplies gasoline under high pressure to the fuel injectors, which deliver it to the cylinders.

The engine runs as the battery feeds electric power through the coils. A computer in the engine signals each coil to fire each of its two spark plugs at the right time. Sparks from the plugs ignite the fuel, and the pistons go into a rapid, pumplike action. As the pistons move up and down, connecting rods turn the crankshaft. The rods transfer energy from the power stroke to the crankshaft and flywheel, which transmit energy to the car's transmission. The engine is now providing the power to move the car.

valve, allowing the pressurized fuel to spray out. See the article **Fuel injection** for more information.

Some older cars use a device called a carburetor to provide the fuel-air mixture. But fuel injection has largely replaced the carburetor. In a carbureted engine, it is difficult to control the fuel precisely enough to achieve the low emissions and the fuel efficiency demanded in today's cars. See **Carburetor**.

The exhaust system works with the emission control system. The exhaust system removes the burned gases from the engine, and the emission control system reduces air pollution.

Even with precise fuel injection controls, the engine does not burn all the fuel completely and so produces emissions that may be harmful. The burned and partly burned gases leave the engine and enter a pipe or set of pipes called the *exhaust manifold*. They then go through the exhaust pipe to the catalytic converter. The interior of this device is divided into honeycomblike cells or, less commonly, is packed with tiny pellets. The cell walls or pellets are coated with certain rare metals, such as platinum, palladium, and rhodium. As the exhaust flows over the metals, a chemical process occurs that breaks down the pollutants into safer emissions. See **Catalytic converter**.

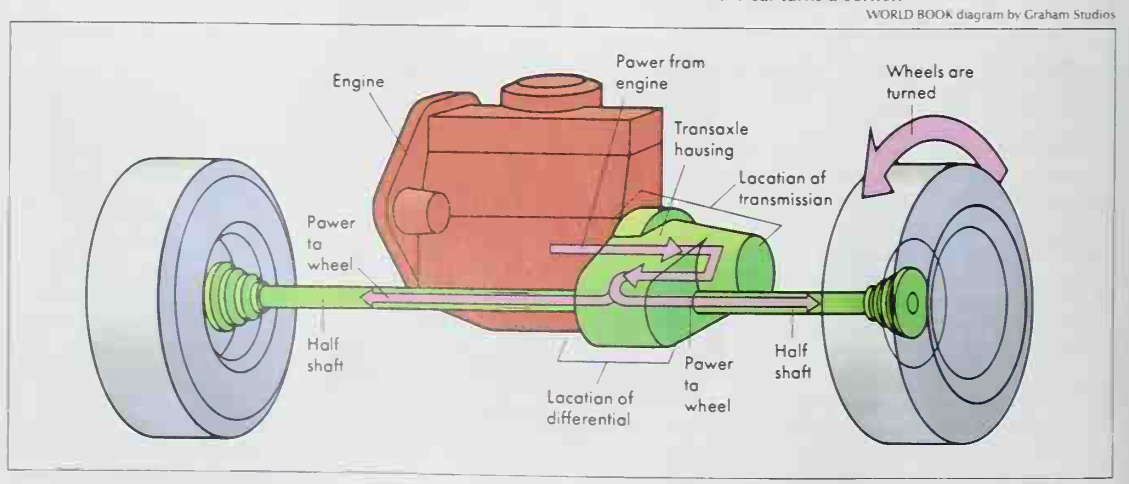
Next, the exhaust gases pass to the muffler. Exhaust leaves the engine rapidly and at a far higher temperature than the outside air. If released directly into the air, the exhaust would expand suddenly and create loud noise. A muffler uses a series of tubes pierced with holes to cool and slow the exhaust before it exits the car through the tail pipe. See **Muffler**.

While a car is moving or parked in the sun, gasoline evaporates from the vehicle. This evaporation can release harmful hydrocarbons into the atmosphere. A separate system controls such emission by collecting the vapors and channeling them to the engine for burning.

The cooling system keeps the engine from overheating, which could damage it. Most automobiles use a *coolant* consisting of about half water and half antifreeze. A pump on the front of the engine circulates the coolant through passages called *water jackets*, which surround the cylinders. The coolant absorbs engine heat as it flows through the water jackets. The heated coolant then passes through copper or aluminum tubes in the radiator. Copper or aluminum fins around the tubes absorb heat from the coolant in the tubes. The motion of the car and, at slower speeds, the action of a fan, draw air through the radiator. As the air moves between the fins, it absorbs their heat. The cooled coolant returns to the engine, and the process starts over. A thermostat controls the engine temperature by regulating the flow of coolant through the radiator.

The lubrication system delivers oil to the moving parts of the engine. As the oil circulates through passages in the engine, it spreads a film on the parts. Lubrication reduces friction and so minimizes engine wear. The oil also helps cool the engine. Oil is stored in a pan under the engine. A pump circulates oil from the pan through a filter and then through lines to the engine. The filter prevents impurities from entering the engine.

The power train, also called the *drive train,* transmits power from the engine to the *driving wheels*—the wheels that make a vehicle go. The power train's parts include (1) the transmission and (2) the drive system.



The transmission gets power from the rotary movement of the *flywheel,* a heavy disk that is turned by the crankshaft. This rotary movement has two related aspects: *speed* and *torque*. Speed refers to the rate of rotation, and torque to twisting force. The transmission uses gears to vary the ratio of speed to torque. For example, a car requires great torque to be put into motion from rest. But as the car moves, it needs less torque and more speed. The *first gear,* also called *low gear,* provides the greatest torque and lowest speed. As the car goes faster and the transmission shifts to higher gears, torque decreases and speed increases.

If a car has a manual transmission, the driver shifts gears with a *gearshift*. After the car has been put into motion and gains speed, the driver shifts to *second gear*

Transferring power to the wheels

The drive train carries power from the engine to the wheels. A key part of the drive train in a front-wheel drive car is the transaxle, which consists of the transmission and the differential. The transmission has gears that vary the speed and *torque* (twisting force) of the engine power. The differential enables the outside front wheel to rotate faster when the car turns a corner.

WORLD BOOK diagram by Graham Studios

Steering the car The steering system guides the front wheels. The steering wheel sits atop the steering shaft. When the driver turns the steering wheel, the steering shaft twists. The twisting operates the steering gears. The gears push and pull on the tie rods, causing the wheels to turn in the desired direction. With power steering, an engine-powered *hydraulic* (fluid) system helps operate steering gears.

WORLD BOOK diagrams by Graham Studios

As a driver turns the steering wheel, the *pinion—a circular gear—*forces the *rack—a flat bar gear—*to move in the opposite direction. The rack pushes and pulls on the tie rods, turning the front wheels in the same direction that the steering wheel was turned.

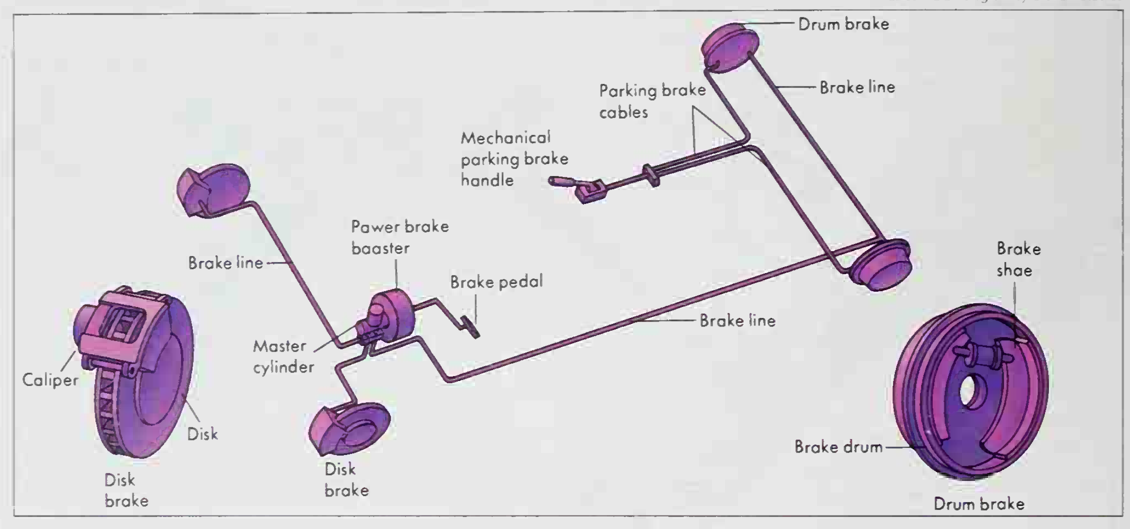
and then to higher gears. Most manual transmissions in new cars have five forward speeds and one reverse gear. When shifting gears, the driver must step on the clutch to disconnect the engine from the transmission.

If a car has an automatic transmission, the driver does not have to operate a gearshift and clutch. To move ahead, the driver simply slides the *selector lever* to the *drive* position. A microcomputer and hydraulic oil pressure control the transmission on the basis of the car's speed, shifting to the gear that is best for a given driving condition. In new cars, most automatic transmissions have three or four forward speeds and one reverse gear. A *torque converter* connects the flywheel to the automatic transmission. A torque converter increases torque. It also enables the driver to have the transmission in gear with the engine running slowly while keeping the car from moving by lightly braking. See **Transmission.**

The drive system carries the engine's power from the transmission to the wheels that move the car. Depending on the automobile, these may be the front wheels, the rear wheels, or both sets of wheels.

In a car with *front-wheel drive,* the front wheels not only steer the vehicle but also drive it. A front-wheel drive combines the engine, transmission, and *differential* under the hood. The differential is a set of gears that enables an outside wheel to rotate faster than an inside wheel as the car turns a corner. The outside wheel travels farther when cornering, and so it must rotate faster to cover more ground in the same time. Power from the transmission is transferred through the differential to each front wheel by a short bar called a *half shaft.* Cars with front-wheel drive can be more compact than those with rear-wheel drive. They also may have less power and cost less to buy and operate. Most passenger cars and vans for private transportation are front-wheel drive vehicles.

Cars with *rear-wheel drive* have a long *drive shaft* to transfer power to the back wheels. The differential is attached to the rear axle. Rear-wheel drive provides better weight distribution, front to back, than does front-wheel drive. Better weight distribution improves a car's handling performance. Most pick-up trucks and vans for commercial use have rear-wheel drive, as do many sport utility vehicles (SUV's).



A vehicle with *four-wheel drive* delivers power to all four wheels. A *transfer case* distributes the power between the front and rear wheels. Four-wheel drive provides good traction on rough or slippery terrain. Many light trucks and SUV's and some cars come with four-wheel drive. In many vehicles, the driver can switch back and forth between four-wheel drive and two-wheel drive.

Control systems include (1) the steering system and (2) the brake system.

The steering system controls the front wheels. The driver operates it with the steering wheel, which is atop the steering column. Most new cars have a steering system with *rack-and-pinion gears.* The pinion is a circular gear at the lower end of the steering shaft. The pinion's

Stopping the car The brake system slows or stops the car. Most cars have disk brakes on their front wheels and drum brakes on their rear wheels. Hydraulic pressure operates both types. Pressing the brake pedal forces fluid from the master cylinder through the brake lines to the brakes. The pressure of the fluid forces a friction material to rub against the disks or drums on the wheels.

WORLD BOOK diagram by Graham Studios

teeth fit into the teeth of the rack, a flat bar gear. As a driver turns the steering wheel left or right, the pinion forces the rack to move in the opposite direction. The rack turns the wheels in the direction opposite of its own by means of a *tie rod* connected to each wheel. Many cars have *power steering,* in which a hydraulic system helps force the rack. A driver can turn the steering wheel far more easily with power steering.

The brake system slows or stops an automobile. Cars have brakes on all four wheels. All autos use *disc brakes* on the front wheels, and most use *drum brakes* on the rear wheels. Some cars have four-wheel disc brakes. Hydraulic pressure operates both types of brakes. When a driver steps on the brake pedal, brake fluid goes through brake lines to each wheel. The pressure of the fluid forces a friction material to rub against the discs or drums attached to the moving wheels. The resulting friction slows or stops the wheels.

Cars with *power brakes* use the difference in pressure between the engine and the surrounding atmosphere to help force the fluid through the brake system. Power brakes make it easier to push the brake pedal, but they do not stop a car any faster than regular brakes. Many cars have an *antilock-brake system,* which keeps the wheels turning in certain circumstances after the brakes have been applied. The system helps keep a car from skidding and is especially useful on wet roads. A computer controls the antilock system. See **Brake**.

The support system. The tires, wheels, axles, and suspension system support the weight of a car. In the past, the frame—a rectangular arrangement of heavy steel tubes—formed the bottom of the car and supported the weight of the car's body. Most cars today do not have a separate body and frame. Instead, they are constructed with a *unitized body,* made of steel panels welded together to form the engine compartment, the passenger compartment, and the trunk. The underbody panels are welded to the body panels.

The suspension system enables the wheels to move up and down with variations in the road surface. It thus helps protect the car body and mechanical parts from the shock of bumps and holes. It also provides better steering control and adds to the comfort of a car's occupants.

Most suspension systems consist of springs and devices called *shock absorbers* or simply *shocks.* A spring and shock are attached to each wheel. As a tire hits a bump, the wheel is forced upward and the spring and shock are compressed. As the road levels out again, the spring and shock rebound, which forces the wheel back downward. See **Shock absorber**.

The electrical system drives the starting and ignition systems, the lighting system, and the comfort and convenience systems. A 12-volt battery stores energy for the starter, which begins the operation of the electrical system by cranking the engine to life. As a car runs, an engine-powered alternating-current generator—better known as an *alternator*—produces power for the electrical system and recharges the battery. See **Battery; Electric generator; Ignition; Starter**.

Comfort and convenience systems. Dashboard instruments provide the driver with certain information. A speedometer measures a car's speed, and an *odometer* records the total distance a car has been driven. A fuel gauge tells how full the gas tank is. Many cars have gauges that record oil pressure, battery voltage, and the temperature of the engine coolant. Other cars have warning lights to alert the driver to problems with oil pressure, battery voltage, and engine temperature.

Virtually all cars come with a heater, which blows air warmed by engine heat into the passenger compartment. Many cars also have an air conditioner, an option that draws on engine power to produce cool air. Other optional devices include audio equipment, power door locks, power windows, and power mirrors. A computer-operated mechanism called *cruise control* makes it pos-

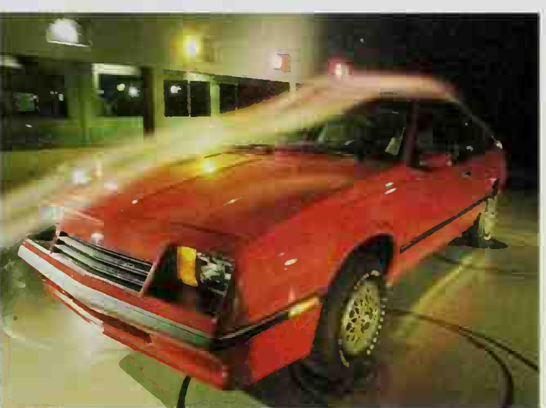
sible for a driver to cruise at a desired set speed without stepping on the gas pedal.

Building an automobile

Most automakers bring out new models every year. But high costs prevent them from making major changes or introducing an entirely new car very often. Manufacturers make mostly minor yearly changes to add features, to meet new standards, to correct problems in earlier models, or to give the car a fresh look and so attract buyers.

Developing a new vehicle—whether it is a major model change or the introduction of an entirely new make—is a task that requires many people, many processes, and many parts. From the initial idea of what the car will be like until the first one is sold takes two to four years. Automakers must therefore try to predict what the market conditions, consumer tastes, and products of their competitors will be several years ahead as they begin designing and developing a new automobile.



Market research typically serves as the first step in developing a new car. Manufacturers survey auto owners and people in the age or income group the vehicle is aimed at to learn their likes and dislikes. They also try to foresee people's concerns in such areas as safety and the environment. Above all, automakers try to forecast the demand for different kinds of vehicles, such as small and large cars, trucks, and minivans.

Designers, engineers, marketing executives, and financial officers study the market research. If a particular market—for example, people wanting small economy cars or large luxury automobiles—appears big enough for profitable production, the firm's top executives may approve the new car program. Such a program may cost hundreds of millions of U.S. dollars—or up to several billion dollars if it requires new assembly and engine plants.

Development of the concept begins after research has identified the market for the vehicle. Automotive designers create exterior colors, interior fabrics, and overall car design. They make hundreds of drawings based on such factors as the potential buyers' tastes, age, and income. The designers may work for the manufacturer or an independent design firm. The design staff chooses the best drawings for review by corporation executives, who make the final selections. Designers enlarge those drawings to full scale. Today, most of the design drawings are created on a computer. This process, called *computer-aided design* (CAD), enables automotive designers to create, test, and modify their plans all on the computer.

Clay modelers turn the drawings into a *concept car*—a full-sized model that resembles a real car. They cut and shape the clay with machine tools that use data and instructions obtained from the drawings. The modelers also use hand tools to carve some tricky bends and openings in the car body. They then apply adhesive film to the clay. The film reflects light, which makes the shiny model resemble what the new car will look like in the dealer's showroom. While artists make this model, other specialists create interior models of the car's seats and instrument panel.

The auto industry's rapidly expanding use of computers to simulate physical properties and events is reducing the time it takes to bring a vehicle to market. The in-

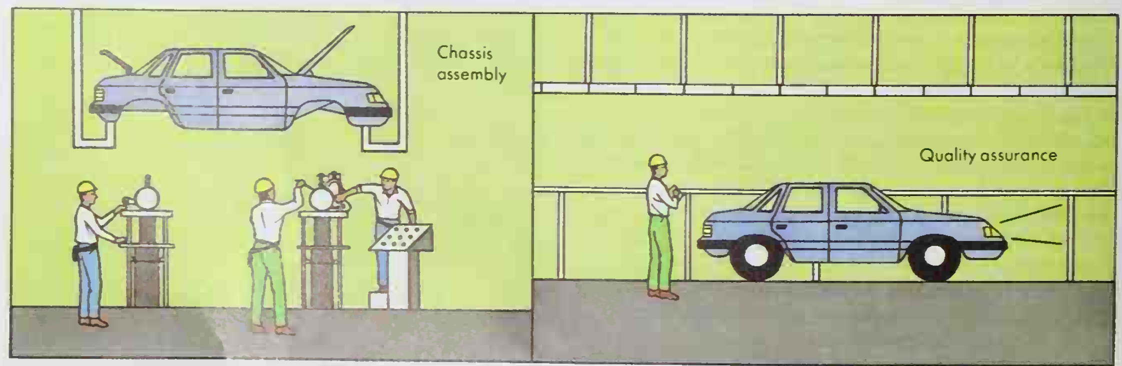
A wind tunnel can be used by automotive engineers to test the effects of airflow on a new car prototype. The tunnel blows a stream of air at the car at a uniform speed.

Assembling an automobile



The drawings below show some of the chief steps involved in assembling an automobile using *unitized body construction.* In this method of assembly, manufacturers build the car body and attach the engine and other chassis parts to it along a main assembly line. Assembly and testing includes about 1,800 separate operations and takes about two days from start to finish.

Assembling the body. After the main body parts are brought together for assembly, computer-controlled welding robots automatically weld the parts together, *above left.* Then, devices called *automatic optical scanners* use laser beams and electronic cameras to check the body, *above right.* They measure the parts to make sure they fit together accurately.

Painting the body. The body is dipped in a tank of *primer*—a paint that helps protect the body from rust. Automatic devices called *electrostatic reciprocators* spray on the final coats of paint. The fine droplets of paint are electrically charged so that they are attracted to the surface of the automobile body, which has an opposite charge. In this way, little paint is wasted.

WORLD BOOK illustrations by Tony Crnovich, Koralik Associates

Chassis assembly and quality assurance. After the body has been painted, the chassis—including the engine, axles, and wheels—is attached to it. The windows, seats, and trim are also added. The car is tested at several points during assembly. At the quality assurance station at the end of the assembly line, technicians make a final check of the car's interior and exterior.

dustry uses fewer clay models than in the past, and simulation is replacing many, but not all, repetitions of tests, such as wind tunnel tests for aerodynamics.

Workers next build a fiberglass body model based on the clay model and interior models. The fiberglass body model is given real tires, glass windows, doors, and interior and exterior trim. It looks as much like a final production vehicle as possible. After further reviews of the program and management approval, development of the new car begins in full force.

Product engineering. A team of automotive engineers plans, coordinates, and carries out the specifications for the new car and the engineering of every needed part. In addition to the manufacturer's engineers, the team may include engineers from automotive suppliers and from independent engineering firms.

Some parts, such as the engine and transmission, need not be developed for a new vehicle if the automaker has appropriate designs. But many parts are newly created. Everything from steering wheels and road wheels to headlights and taillights must be specified. Computers now handle a large portion of automotive engineering. Engineers rely on *computer-aided engineering* (CAE) programs to design and draw parts, to combine the parts into *components,* and to package the components into a car's systems. In CAE, a scanner traces every line and curve on the clay model, gathering information that is stored in the computer. The computer is then used to produce engineering drawings for making *dies*—the precision tools that shape metals and other materials for the parts and components.

As parts and components are engineered, manufacturers have *prototypes* of the vehicle assembled to test its design and engineering. The prototypes may look nothing like the final car. American automakers test prototypes on *proving grounds* in the dry heat of Arizona, the humid heat of Florida, and the cold of northern Canada. The prototypes put on tremendous mileage and may be modified again and again until the manufacturer is satisfied with the quality and cost of the components.

Automakers also use prototypes to test the planned car's endurance and emissions control. The emission-control tests involve running the prototypes 24 hours a day to cover 100,000 miles (160,000 kilometers). The endurance tests may cover twice that distance. Prototypes are further used to check a vehicle's safety. As engineers design the body, computers show how well the car will protect occupants in a crash. But actual cars must be crashed into walls to be sure they meet government standards for impact protection. Prototypes cost hundreds of thousands of dollars. If the prototypes fail the tests, they must be redesigned and reengineered until they pass.

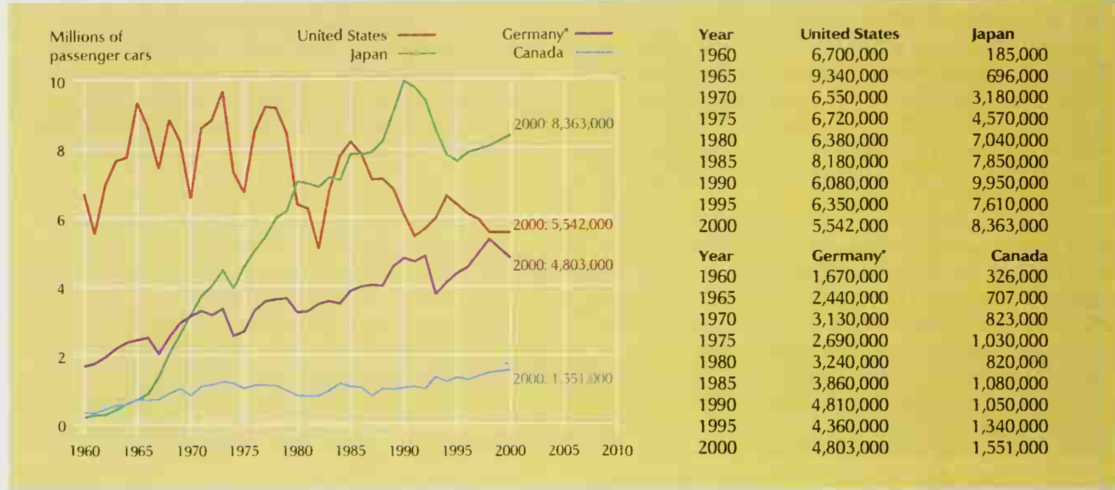
In computer-aided manufacturing (CAM), computers oversee various tasks during auto production. In this assembly line, computers operate robots that weld car bodies.

Manufacturing engineering involves developing the production operations and specifying the equipment needed to make and assemble the final vehicle. Prototypes can help manufacturing engineers improve the production process. Assembly of the prototypes often reveals design problems that can be corrected to make assembly of the final car more efficient.

Materials purchasing is the job of buying from suppliers the raw materials, parts, and components needed to build cars. Automakers prepare specifications for steel, rubber, and other raw materials. For parts and components, a manufacturer might provide the supplier with blueprints to make them. Or the manufacturer might specify the function and maximum dimensions and let the supplier do the designing and engineering. Suppliers often include the manufacturer's internal supplier divisions. Internal and outside suppliers bid for the work.



About 50 percent of the value of European cars and up to 75 percent of the value of Japanese cars comes from outside suppliers. For American cars, the value from outside suppliers ranges from 50 percent to 75 percent, depending on the automaker.

Manufacturing involves making parts and components for the new car and assembling them. Today, computers play a big role in a car's manufacture. Companies use *enterprise requirements planning* programs to schedule the quantities and timing of parts for delivery to their plants. In *computer-aided manufacturing* (CAM), computers operate machine tools that make various parts and components. They also instruct robots that weld and paint the body and do other tasks in assembling the car.

Manufacturing a car requires different processes to produce different parts. In *metal stamping,* presses shape metal into forms determined by dies. Small presses stamp out such parts as brackets. Huge presses stamp out trunk lids, floors, roofs, fenders, doors, and hoods. In *casting,* molten metal is poured into a mold. The engine block is the major part cast. *Forging* shapes steel or iron into desired forms by hammering. Crankshafts and certain pieces of the suspension may be forged. *Machining* involves using various tools to cut, grind, and shape precision parts, such as those in engines and transmissions. Several processes are used to shape a car's plastic equipment.

After the parts and components have been made, the car can be put together on the assembly line, which may turn out up to 75 copies of the car per hour. Final assembly includes welding and bolting the body parts together, painting, installing the engine, attaching the interior parts, and adding options. Assembly lines have become more and more computerized, with robots doing many tasks and cameras and lasers performing inspections. But the assembly plant still requires much human labor

Automobile production in selected countries since 1960

Year	United States	Japan
1960	6,700,000	185,000
1965	9,340,000	696,000

to make sure all parts and components—and the assembly itself—are of the highest quality.

The automobile industry

The auto industry has become increasingly internationalized. During the early 1920's, the United States made about 90 percent of the world's cars. By the late 1990's, it made about 20 percent. Yet U.S. output has generally climbed since the 1920's. What has happened is that worldwide production has skyrocketed—from about 10 $\frac{1}{2}$ million motor vehicles in 1950 to more than 50 million in the early 2000's.

Compact cars and the even smaller *subcompacts,* as a rule, cost the least to buy and operate. Larger mid-size cars offer greater styling and room. Snappy sports cars and convertibles appeal to many of the young and young at heart. Vans, trucks, and SUV's also serve the lifestyle and personality of certain car buyers today. Luxury automobiles attract wealthy buyers.

People in different countries often have different preferences for automobiles. For example, European drivers are much more likely to drive smaller passenger cars and to prefer manual transmissions than U.S. drivers. United States and Canadian drivers are more likely than Japanese drivers to choose pickup trucks, vans, and SUV's over traditional passenger cars.

Major producing countries and companies. In the value of its products, the automotive industry leads all other manufacturing industries in Japan, the United States, and a number of other countries. Most developed nations produce motor vehicles. Many developing nations also manufacture cars and trucks or assemble them for automakers of other countries. In addition, more than 100 countries make parts and components.

The United States and Japan are the largest motor vehicle producers. Major producers also include France, Germany, South Korea, and Spain. In general, the largest automaking countries also have the largest markets for cars. The United States has the biggest car market by far. Most countries with a large auto industry and a large car market have a heavy import and export trade in cars. Japan and the United States are the chief exceptions.

Automobile registrations in the United States and Canada since 1900

Year	United States	Canada
1900	8,000	—
1905	77,000	600
1910	458,000	6,000
1915	2,332,000	61,000
1920	8,132,000	252,000

Japan imports a small share of the cars sold at home, and the United States exports many vehicles to Canada, but only a small portion to other countries.

The largest U.S. automakers are General Motors Corporation and Ford Motor Company. They have thousands of suppliers, including such giant corporations as United States Steel Corporation, General Electric Company, and TRW. Both companies produce, under different trade names, a variety of cars and light trucks designed to meet the needs, preferences, and incomes of different consumers. The two companies, along with a third U.S. manufacturer, Chrysler Corporation, were long known as the Big Three. Chrysler merged with Germany's Daimler-Benz in 1998 to form the international automaker DaimlerChrysler AG.

Japan's major producers include Toyota Motor Corporation, Nissan Motor Company, and Honda Motor Company. Historically, Japanese cars made for use in Japan have tended to be small, fuel efficient, and of limited power. This is because Japan depends completely on imported oil and many of its streets are too narrow and crowded for big cars. For export, Japan produces a range of models to satisfy a variety of buyers.

Many European companies make far fewer vehicles than do Japanese or American firms because they target their output to the smaller luxury and sports car markets. Such European producers include BMW and Porsche of Germany. Other European manufacturers produce millions of cars each year. These major producers include Volkswagen of Germany; Peugeot and Renault of France; and Fiat of Italy.

Some large manufacturing concerns own or control several automobile companies, often in more than one country. For example, Volkswagen owns the luxury car manufacturers Audi of Germany and Rolls Royce of the United Kingdom. Ford owns Jaguar of the United Kingdom and Volvo of Sweden. It also owns a controlling interest in Mazda, a Japanese manufacturer. Renault owns a significant share of Nissan. General Motors owns Saab of Sweden and controls Isuzu and Suzuki of Japan.

Economic importance of the auto industry extends far beyond making motor vehicles. Although this activity

Japanese cars for export are loaded aboard this ship docked at Yokohama, Japan. Japan makes more passenger cars than any other country in the world and is the world's leading exporter of automobiles.

©Cameramann International, Ltd.

provides millions of jobs, supplier industries employ even more people. And still more millions work in such related businesses as service stations, repair shops, and car rental agencies.

Manufacturing jobs in the auto industry generally pay well and offer good benefits. Production workers earn the most money and receive the best benefits in developed countries. But even in developing nations, workers make two or three times more in automotive production than in other manufacturing activities.

The auto industry also aids the economies of many countries by its huge consumption of the output of other industries. For example, the typical passenger car requires about 1,790 pounds (810 kilograms) of steel; 380 pounds (170 kilograms) of iron; 240 pounds (110 kilograms) of plastics; 210 pounds (100 kilograms) of aluminum; and 140 pounds (60 kilograms) of rubber.

Because automobile manufacturing generates and supports a broad range of businesses, it can spur growth in developing countries. Many such nations therefore try to establish an automotive industry. They also hope to export vehicles to earn money with which to buy needed imports. The developing nations of South Korea and Yugoslavia attempted to become major car exporters in the 1980's. South Korea has had much greater success than Yugoslavia. During the mid-1990's, South Korea exported about a third of its car production.

Careers. Rewarding careers can be made in each of the auto industry's three main activities—manufacturing, selling, and servicing.

Manufacturing hires college graduates trained as chemists, engineers, metallurgists, or physicists. Some perform research to develop the materials, processes, and machinery needed to make cars. Others work with artists, designers, and drafters to create new models. The industry also hires college graduates trained in economics, journalism, marketing, statistics, business administration, or industrial management.

Most workers who assemble cars or make parts and components are trained on the job. Some jobs require skilled workers, including machinists, patternmakers, and tool and die makers. Such workers may spend four to six years as apprentices, learning on the job and receiving classroom training in mathematics, computer technology, blueprint reading, and mechanical drawing. Some car manufacturers and autoworkers' unions run joint apprentice programs. High school students wanting jobs in automobile trades should take shop, math, and computer courses.

Selling new or used cars for dealers often requires a forceful personality. Experience as a mechanic or in business can be especially useful to *jobber salespeople.* They sell automobile parts wholesale to garages and car dealers. Companies that make materials or parts for car manufacturers also hire salespeople.

Servicing. Many young people work in garages, gasoline stations, or the service departments of car dealers. Such young people may learn car repair from experienced mechanics. Most workers in dealer service departments receive training in the shop from the automaker's *factory service instructors.* Some workers become *specialty mechanics,* experts in repairing certain parts or systems of a car. A car dealer's service department is headed by a *service manager,* who schedules all repairs and assigns the jobs to mechanics. A *parts manager* makes sure the service department has enough parts on hand.

Driving safely

Most people find it easy to drive a car. But operating an automobile is a complicated and demanding task—and driving safely is not easy.

Learning to drive. Most automobile accidents involve drivers who violate traffic laws, lack good driving skills, or ignore or are unaware of the rules of safe driving. For that reason, in many countries, a new driver can be granted a license to operate a car only after passing a series of tests, including a road sign test, vision test, road rules test, and driving test. In the United States, most states require a person to be at least 16 years old to be given the privilege of driving. State driver's license bureaus stress that a driver's license is a

Do's of safe driving

Fasten your safety belt snugly before starting the engine.
Drive defensively—always think ahead.
Obey all traffic regulations.
Drive at a safe speed.
Reduce speed at night, in bad weather, and in heavy traffic.
Yield the road to emergency vehicles that flash a light or sound a siren. Pull far to the right and stop.
Drive in the passing lane only when passing.
Allow vehicles behind you to pass when drivers indicate they want to do so and passing conditions are favorable.
Signal by hand or light your intention to turn, pass, or change lanes.
At intersections, yield the right of way:

1. To pedestrians.
2. To drivers ahead of you.
3. To a driver on the right, if you both arrive at an intersection at the same time.
4. To through traffic, if you are turning left.

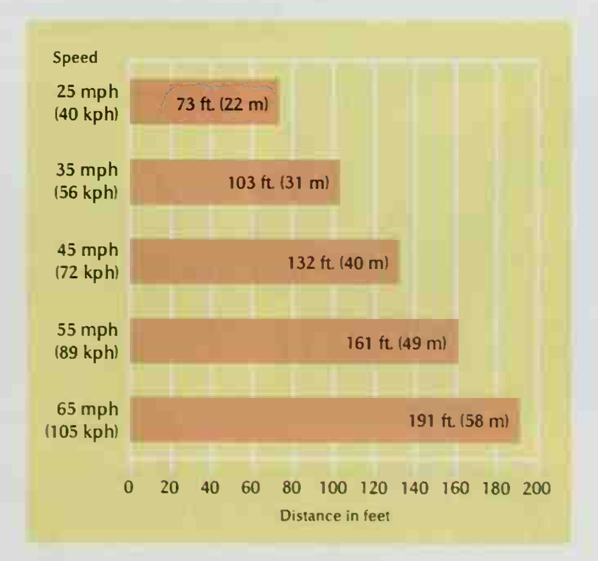
Don'ts of safe driving

Never pass a car unless you have plenty of open road ahead. Come back into line only after the car you have passed is visible in your rear-view mirror.
Never pass a stopped bus without taking precautions. A passenger may step into your path from in front of the bus.
Never park with any part of your car in a driving lane.
Never coast with gears in neutral.
Never weave from lane to lane in traffic.
Never cut across a curve.
Never drive past a STOP sign without stopping, even though there is no traffic, and even though the car ahead of you has halted and moved on.
Never pull into traffic until your car's engine is running smoothly.
Never park a car facing traffic. It confuses other drivers, especially at night, and is illegal in most places.
Never drive with your bright lights on when other cars are approaching, or when following another car.

privilege, not a right. Careless, unsafe drivers who break traffic laws risk losing their licenses.

A qualified instructor provides the best way to learn how to drive. Many teen-agers learn to drive by taking driver education classes in high school. Commercial driving schools also teach beginning drivers. Before learning to drive, a student must obtain a restricted operator's license, also known as a provisional license or learner's permit, to practice driving. Only qualified and experienced adult drivers should accompany a student who is practicing. Classroom instruction and practice driving help students sharpen their driving skills and master the techniques of controlling a moving vehicle. They also learn about the responsibilities involved in driving a car.

Responsibilities of driving. Operating a car involves certain responsibilities to oneself and to others. First of all, a driver must be continuously alert while making a variety of maneuvers, such as speeding up, slowing down, changing lanes, turning, and stopping. At the same time, the driver must be aware of other motor vehicles (including motorcycles), pedestrians, bicyclists,



Standard traffic signs

The main aids to safe driving are the traffic signs seen on all American highways. These signs (1) regulate traffic, (2) warn of dangerous road conditions, or (3) give vital information.

Octagon		Always requires a complete stop—not merely a slowdown.
Round		Always means there is a railroad crossing just ahead.
Diamond		Always warns of a certain danger, such as a sharp curve.
Triangle		Always means yield the right of way by slowing or stopping.
Rectangle		Always gives important instructions or directions.

Safe following distances

A driver can determine the safe following distance by using the *two-second rule.* The driver selects a fixed object in the road ahead. When the vehicle ahead passes the object, the driver counts "one-thousand-one, one-thousand-two." If the driver's vehicle reaches the object before the count is completed, he or she is following too closely. If road or weather conditions are not good, the driver should increase the count to four or five seconds. The graph below shows some safe following distances based on the two-second rule.

various road signs, and road hazards. Decisions must be made quickly and correctly. Drowsiness or illness slows a driver's ability to react rapidly to changes in traffic conditions. Driving under the influence of alcohol or drugs is especially dangerous.

A good driver concentrates on only one thing while driving—the driving itself. Drivers who become distracted by cellular phone use or by other activities cause many accidents. A good driver also has a proper attitude, which means a willingness to share the road with others. Aggressive behavior—driving too fast, following another vehicle too closely, or rapid lane changes—may cause a driver to lose control of the car or provoke angry reactions in other motorists. Finally, drivers have the responsibility to see that their cars are properly maintained.

Defensive driving means anticipating danger to avoid accidents. A defensive driver stays alert to all possibilities, such as other vehicles slowing down, entering the roadway, or stopping suddenly. A defensive driver adjusts the car's speed and position to suit visibility, the road, and traffic conditions; slows down before entering a curve; yields the right of way; and signals well in advance before turning or changing lanes.

History of the automobile

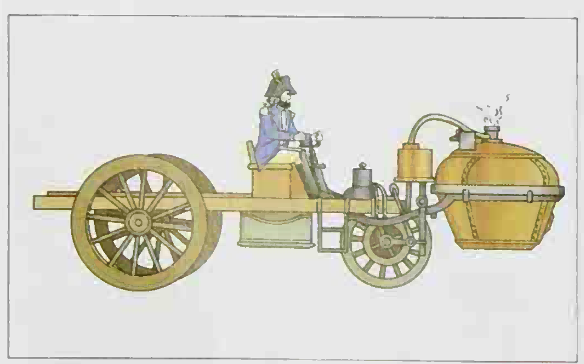
The first cars. During the late 1700's, the development of steam-powered engines progressed rapidly in Europe. Inventors dreamed of a "horseless carriage"—and steam seemed the obvious power source.

The steam car. Nicolas-Joseph Cugnot, a French military engineer, built the first self-propelled road vehicles in 1769 and 1770. One was designed to carry passengers, while the other was a three-wheeled steam tractor for hauling artillery. In 1801 and 1803, Richard Trevithick of the United Kingdom demonstrated four-wheeled steam-propelled road vehicles to carry passengers. But he lacked the money to continue his work.

Numerous attempts in the United Kingdom to promote the use and development of steam cars failed because of competition from railroad and stagecoach companies. Early steam cars damaged roads and sometimes blew up. They also made a terrible racket, dirtied the air with smoke, and frightened horses. In 1865, the "Red Flag Law" ended further development of automobiles in the United Kingdom for about 30 years. Under the law, a steam car could go no faster than 4 miles (6 kilometers) per hour in the country and 2 miles (3 kilometers) per hour in town. To warn of its approach, a signalman had to walk ahead of the vehicle, swinging a red flag by day and a red lantern by night.

In 1805 in the United States, an inventor named Oliver Evans demonstrated a steam-operated dredge mounted on a boat. He had built it to deepen and clean the Philadelphia waterfront. Evans put wheels on the boat and drove the gigantic machine, which weighed about 20 tons (18 metric tons), through the streets to the harbor and into the water. During the 1860's, another American inventor, Sylvester H. Roper, developed a much smaller steam vehicle. It looked more like a present-day automobile. Roper's vehicle received much public attention.

Many other Americans experimented with steam cars during the late 1800's. They included J. N. Carhart, Richard Dudgeon, and Ransom E. Olds. The number of



Highlights in the history of the automobile

1769-1770 — Nicolas-Joseph Cugnot of France built two steam-powered road vehicles.

1801-1803 — Richard Trevithick of England developed a four-wheeled steam carriage for transporting passengers.

1860 — Jean Joseph Étienne Lenoir of France patented an internal-combustion engine.

1865 — England passed the "Red Flag Law," which ended development of automobiles there for about 30 years.

WORLD BOOK illustration by Oxford Illustrators Limited

The Cugnot steam tractor was one of two steam-powered road vehicles built by French military engineer Nicolas-Joseph Cugnot in 1769 and 1770. These were the first self-propelled road vehicles.

Six-wheeled steam carriages provided regular passenger service in England in the mid-1800's. By the late 1800's, opposition by railroad and stagecoach companies had effectively ended the use of such steam carriages in England.

U.S. companies that made steam cars grew rapidly. One of the most successful firms was founded by identical twin brothers, Francis E. and Freelan O. Stanley. They built the famous Stanley steamer.

Steam cars had big disadvantages. At first, it took too long for the fire to heat the boiler. Inventors solved that problem, but others remained. The steam engines had to be small to be practical for cars, and so they had to be high-pressure engines to produce the required power. However, such engines cost much to build and maintain, and the steam-powered car gradually disappeared. In 1924, the Stanley brothers' company—one of the last steam car manufacturers—went bankrupt.

The electric car. About 1891, William Morrison, an American inventor, built a successful electric car. The six-passenger vehicle was powered by batteries under the seats. Electric cars quickly became popular because they were quiet, easy to operate, and free of smelly fumes. In 1900, they accounted for 38 percent of all U.S. car sales. But the batteries limited how far or fast electric cars could go. Few electrics could travel faster than 20 miles (32 kilometers) per hour, and the batteries had to be recharged at least every 50 miles (80 kilometers). By 1905, only about 7 percent of all cars sold in the United States were electrics. See Electric car.

The gasoline car. The automobile as we know it today resulted from the development of the internal-combustion engine. Jean Joseph Étienne Lenoir, a Belgian living in France, patented the first commercially successful internal-combustion engine in 1860. It burned coke oven gas and was noisy and inefficient. But Lenoir sold several hundred engines, which powered printing presses, lathes, and water pumps. He also installed one in a crude motorcar.

In 1885, Gottlieb Daimler and Karl Benz, two Germans working separately, developed the first successful four-stroke gasoline engines. Their engines led to the development of those used in most cars today. Many European manufacturers turned out cars based on Daimler's and Benz's work and patents. In 1891, a French company, Panhard et Levassor, created the basic design for the automobile that remained largely unchanged for nearly 100 years. The firm placed a Daimler engine in the front of the car and used a revolving chain to transfer power to the rear wheels. In 1898, the French inventor Louis Renault replaced the chain with a drive shaft. Most cars had a front engine and rear-wheel drive until the mid-1980's, when front-wheel drive began to predominate.

A French rubber-making firm, Michelin, introduced the first tires filled with compressed air for use on cars in 1895. Michelin developed such *pneumatic tires* under license from a British manufacturer of bicycle tires. Many people believe that the automobile became a practical means of transportation because of, first, the invention of the internal-combustion engine and, second, the development of the pneumatic tire.

The birth of the automobile industry occurred in 1885, the year Daimler and Benz built their successful gasoline engines. Until 1900, Europe led the world in automobile development and production. Many present-day European car companies began in the late 1800's. For example, Peugeot, a French firm, started making automobiles in 1890. Another French company, Renault, began producing cars in 1898. Fiat of Italy dates from

1860's — American inventor Sylvester H. Roper built a steam-powered vehicle that received much attention.

1885 — Gottlieb Daimler and Karl Benz of Germany developed forerunners of the gasoline engines used today.

c. 1891 — William Morrison of Des Moines, Iowa, built a six-passenger car powered by electricity.

1891 — The French company Panhard et Levassor designed a front-engine, rear-wheel drive auto.

Mercedes-Benz

The Benz carriage was one of the first vehicles powered by a four-stroke gasoline engine. Karl Benz and Gottlieb Daimler developed the engine separately in 1885.

State Historical Society of Iowa

An electric car built by William Morrison in the early 1890's became the first successful vehicle of its kind produced in the United States.

Free Library of Philadelphia

The Panhard et Levassor was the first gasoline-powered car with a front-mounted engine and rear-wheel drive.

1899. France and Germany became the first large production centers.

The Duryea brothers, Charles E. and J. Frank, built the first successful gasoline car in the United States. The Duryea car was completed in 1893 and made its first successful run in 1894. In 1895, the brothers founded the Duryea Motor Wagon Company, the first U.S. firm to make gasoline cars. Many other automaking firms were started in the United States during the industry's early years. Some quickly failed, but others still produce vehicles. The center of the auto industry shifted from Europe to the United States after 1900. Production of American cars increased from fewer than 5,000 in 1900 to more than 1 $\frac{1}{2}$ million in 1916.

From the beginning, the auto industry had an enormous impact on Western economies. As car production increased, the demand for steel, rubber, glass, machine tools, and other goods essential to the manufacture of the automobile grew and grew. At the same time, the industry began to develop its own supporting divisions for sales, service, and repairs. Employment in the automotive industry soared.

The discovery of huge oil fields in eastern Texas in 1901 helped contribute to the rapid growth of the U.S. auto industry. The discovery caused a sharp drop in the price of gasoline, and plentiful, cheap fuel made cars relatively inexpensive to operate. Another factor aiding the U.S. auto industry was the application of mass-production techniques to the manufacture of automobiles. Prior to 1900, carmakers had used skilled workers to assemble each automobile. But American manufacturers had been using mass-production techniques since the mid-1800's to make such products as firearms and farm equipment, and it was inevitable that they would apply this process to carmaking. Once established, mass production brought the price of U.S. cars down to a level that many people could afford. By the early 1900's, a buyer in the United States could choose among a variety of cars costing less than $1,000, while elegant European models, most of which were still handcrafted, sold for more than $2,000 in U.S. dollars.

Many historians credit the 1901 Oldsmobile with being the first mass-produced car. More than any car before, this automobile was built of parts made by outside suppliers and shipped to the assembly plant. Mass production took a giant step forward in 1904, when Henry M. Leland took charge of the Cadillac Automobile Company in the United States and began building cars using interchangeable parts. Such parts could be used to assemble or repair any car of the same model. Previously, most parts were made to fit only one particular car.

But more than anyone else, the American industrialist Henry Ford perfected the mass production of automobiles. In 1913, Ford installed a moving assembly line in his car factory. The frame of the car was pulled through the plant by a chain. Workers on each side assembled the car by adding parts that had been brought to them on conveyor belts. This process resulted in a huge cut in production time and costs.

The Detroit pioneers. As the U.S. industry developed, the Northern industrial cities of Cleveland, Chicago, and Detroit produced the most cars. Detroit and its surrounding area soon became the *Automobile Capital of the World* for several reasons. Detroit already had

1893-1894 — Charles E. and J. Frank Duryea demonstrated the first successful American gasoline-powered car.

1895 — The Michelin company of France introduced the first tires with compressed air for use on cars.

1896 — Pioneer automaker Henry Ford built his first successful gasoline-powered car.

1901 — Ransom E. Olds built 425 autos to begin the mass production of cars in the U. S.

1901 — The Spindletop gusher marks the discovery of huge oil fields in eastern Texas.

The Duryea, the first successful U.S. gasoline car, was built by brothers Charles and Frank Duryea in the 1890's.

Smithsonian Institution

The Stanley steamer was one of the most famous steam-powered cars. Francis and Freelan Stanley, identical twin brothers, built the first one in 1897.

Culver

The discovery of huge oil deposits in eastern Texas in 1901 aided the growth of the auto industry by making gasoline more plentiful and cheaper.

many foundries and machine shops and was a center for making cast-iron stoves and marine engines. Nearby Flint was a major producer of horse-drawn wagons and carriages. Detroit's location on the Detroit River made the city a gateway to ports on the Great Lakes. But Detroit's chief advantage over other production centers was that it had a large number of successful pioneer automakers.

Ransom E. Olds began tinkering with steam and electric engines as a teen-ager. While in his 20's, he built his first vehicle—a three-wheeled steam-powered car. He helped found the Olds Motor Works in Detroit in 1899. In 1901, the firm began to mass-produce its famous curved-dash Oldsmobile, a low-cost gasoline car. The floorboards curved up in front, forming a stylish dashboard.

Henry Ford worked as a machinist and engineer in Detroit when a young man. He built his first successful gasoline car in 1896 and founded the Ford Motor Company, his third company, in 1903. His first company failed, and he simply left the second. Ford introduced his famous Model T in 1908. It sold for $825. Through mass production and low production costs, he was able to cut the car's price repeatedly. The key to Ford's success was his moving assembly line, which tripled production to more than 240,000 Model T's a year. The car's price dropped to its all-time low, $290 in U.S. dollars, in 1924. The Model T outsold all other cars for almost 20 years and truly put America on wheels. People called it, with affection, the Tin Lizzie.

William Crapo Durant became a millionaire by making carriages in Flint. In 1904, he took control of the Buick Motor Company, founded by David Dunbar Buick. Durant made Buick a top automaker by 1908. That year, he organized General Motors Company with the goal of making cars in a broad range of sizes and prices. Over the next two years, the company, called GM for short, acquired many other car companies, including Cadillac and Oldsmobile, plus many supplier firms.

Durant lost control of GM in 1910. Charles W. Nash replaced him as president at Buick, and Walter P. Chrysler became Buick's works manager. In 1911, Durant and Louis Chevrolet formed the Chevrolet Motor Company, whose low-priced car became an immediate success. Durant regained control of GM in 1916. Nash, who had served as GM's president since 1912, resigned and formed the Nash Motor Car Company. Chrysler eventually became vice president of GM. Later, he founded the Chrysler Corporation.

The Dodge brothers, John and Horace, originally produced bicycles. In 1901, they opened a machine shop in Detroit and soon built parts for Olds and Ford. The Dodges amassed a fortune from their business and especially from their purchases of Ford stock. In 1914, they began making their own autos, which were among the first American cars with an all-steel body. Buyers liked the new Dodge—and its price. It cost only slightly more than the Model T.

Technological advances came quickly after the birth of the auto industry and helped make cars safer, more comfortable, and easier to operate. One major development was the introduction of the electric self-starter. Charles F. Kettering, an American engineer, invented it in 1911, and General Motors installed the first

1903 — Henry Ford founded the Ford Motor Company.

1904 — Henry M. Leland of the Cadillac Automobile Company began building cars using interchangeable parts.

1908 — Ford introduced the Model T. William C. Durant set up General Motors.

1912 — General Motors introduced the electric self-starter, invented by Charles F. Kettering the year before.

1913 — Ford installed a moving assembly line in his auto factory, dramatically cutting production time and costs.

General Motors Corporation

The curved-dash Oldsmobile, the first mass-produced car, was driven up the steps of the Michigan Capitol in a publicity stunt.

AP/Wide World

Assembly-line methods were improved by Henry Ford. Ford used the moving assembly line to produce the Model T, the most popular U.S. car of the early 1900's.

Motor Vehicle Manufacturers Association

Road building boomed with the increased popularity of the automobile. In 1916, workers began building a nationwide U.S. highway system.

ones in its 1912 Cadillacs. The self-starter ended the need to insert a crank into the front of the engine and then turn the crank by hand until the engine started. Hand-cranking was difficult, troublesome, and sometimes dangerous.

In 1914, most U.S. automakers agreed to share use of one another's patents without cost. This system, called *cross-licensing,* ended in 1956. Since then, the automakers have treated their inventions as private property.

World War I and the Roaring Twenties. World War I (1914-1918) demonstrated the value of motor vehicles for military purposes. In that war, the Allies, who included France, the United Kingdom, and the United States, defeated the Central Powers, who included Germany and Austria-Hungary. In September 1914, German forces advanced on Paris. The French used Paris taxicabs to rush soldiers to the battlefront. In 1916, the Allies saved Verdun, France, from German capture with the help of fresh troops and supplies carried to the front by trucks. Car manufacturers produced large quantities of war goods for the Allies. They made military trucks and tanks, airplane engines, and other military supplies.

People continued to purchase cars for personal use. Automobile production fell for the first time in 1918, reflecting chiefly a shortage of materials. After the war, the industry expanded again.

An economic slump struck the United States in 1920 and 1921. The sagging economy hurt the U.S. auto industry badly and resulted in major shifts in the leadership of the big companies.

Changes at the top. General Motors common stock plunged as car sales dried up. Durant had to leave his post as head of GM for the second time. Alfred P. Sloan became GM's president in 1923. He developed several ideas that the entire industry came to adopt. Sloan sought to stimulate sales by changing model styling each year. The tactic is often described as *planned obsolescence*—the manufacture of products designed to become outdated sooner than might be expected. However, the purpose has never been to build cars that would necessarily have short lives but rather to improve and restyle each year's models and so encourage customers to buy a new car before the old one has to be replaced. Most of the world's large automakers still follow the practice. Sloan also set up a system of group management in which each GM car division would be independent and responsible for its own operations. Yet the head of GM would still have tight control. Sloan thus established an organizational structure for managing the huge companies that the major automakers became.

Leland left Cadillac in 1917 and founded the Lincoln Motor Car Company. But the economic slump damaged the company so severely that Leland sold it to Henry Ford in 1922. The Ford Motor Company then had a luxury car—the Lincoln—to contrast with its Model T. But sales of the Model T declined in the mid-1920's. The economy boomed after the 1920-1921 slump, and people had extra money to spend on cars. Buyers wanted more than just basic transportation. Other companies, especially GM, built cars that offered comfort, styling, and speed at reasonable prices. Henry Ford stopped making the Model T in 1927. He introduced the Model A in late 1927. In 1928, it became the top-selling car.

Chrysler retired from General Motors as a millionaire

1918 — U.S. auto production fell for the first time, as a result of World War I (1914-1918).

1921 — Walter P. Chrysler became president of the company that later became the Chrysler Corporation.

1920's — The Big Three—Ford, GM, and Chrysler—accounted for most U.S. car production.

1922 — Low-pressure, or balloon, tires were introduced, giving a more comfortable ride.

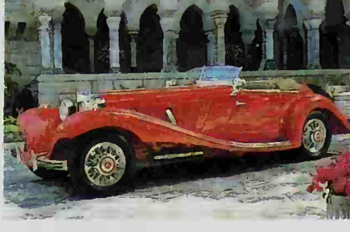
Motor Vehicle Manufacturers Association

Motor vehicles played a major role during World War I (1914-1918). Trucks moved soldiers and supplies from place to place.

Culver

A 1920's boom in the auto industry put more cars on the road in the United States. Traffic clogged 42nd Street in New York City in this 1922 photograph.

General Motors Corporation



GM's Chevrolet became the top-selling U.S. car in the late 1920's, a distinction it held almost every year until the late 1980's. A 1927 Chevy is shown here.

Classic cars The Classic Car Club of America (CCCA) defines a Classic as a "fine" or "distinctive" American or foreign car, built between 1925 and 1948. The CCCA lists about 100 makes as Classics. The typical Classic was high-priced when new and was produced in limited quantities. Its luxury features included a specially built body called "custom coachwork."

1923 — Alfred P. Sloan became president of GM. He introduced new car models every year.

1930 — U.S. motor vehicle production fell 36 per cent due to the Great Depression.

1932 — Production slumped to 1,300,000 vehicles, the lowest number since 1918.

1935 — The United Automobile Workers (UAW) union was founded in Detroit.

1939 — Fully automatic transmission and air conditioning were introduced.

Motor Vehicle Manufacturers Association

The 1932 Ford, *above,* was one of the first cars with a V-8 engine. In spite of its new model, Ford, like most other auto firms, suffered hard times in the 1930's.

Dorothea Lange

Rickety cars carried many farm families to new homes in California during the mid-1930's, after drought in the Great Plains.

AP/Wide World

Strikes by auto workers led to improved wages and working conditions. Workers held a strike at a GM plant in Flint, Mich., in 1936, *above.*

in 1919. In 1921, he became president of Maxwell Motor Corporation and breathed life into the ailing firm. He introduced a new car, which he called the Chrysler, in 1924. It was an immediate success. Chrysler renamed the company the Chrysler Corporation. He bought the Dodge Company in 1928 and introduced two new makes—the De Soto and the Plymouth—in 1928.

The rise of the Big Three. During the 1920's, the large manufacturers cut their profits on each car to step up their sales. Soon, only companies that could make and sell many cars quickly could stay in business. The number of U.S. automakers dropped sharply—from 108 in 1923 to 44 by 1927. Throughout the decade, the Big Three—Ford, General Motors, and Chrysler—produced most American cars. During this same period, these companies also set up factories in Australia, the United Kingdom, and other countries. Small companies, such as Rolls-Royce in the United Kingdom and Packard in the United States, built luxury cars with smart styles and elegant features. These cars became known as *classic cars.*

The new economic giant. The auto industry became a pillar of the U.S. economy in the 1920's. Automobile production climbed from almost 2 million vehicles in 1919 to more than 5 million in 1929. The value of its output exceeded that of any other industry. Furthermore, it had become basic to the well-being of industries that produced the basic materials and tools needed to manufacture automobiles. The establishment of thousands of repair shops, filling stations, restaurants, and lodging places to serve the millions of American motorists further stimulated the economy.

The increasing automobile output reflected the good times of the 1920's. Americans eagerly spent money on new cars. In addition, dealers and manufacturers encouraged people to trade in their old car for a new model or to trade up to a better car. Those who lacked cash could buy on credit.

The hard times of the 1930's. The auto industry suffered severely during the Great Depression, which began in October 1929. In the United States, production of all vehicles fell 36 percent in 1930 and 29 percent more in 1931. In 1932, output plunged an additional 44 percent to about 1,300,000 vehicles, the lowest volume since the war year of 1918.

Because of plant closings and lowered production, autoworkers were periodically jobless during the Depression. Ford and Chrysler lost money, but GM made a profit throughout the 1930's. By the end of the decade, the Big Three controlled over 85 percent of the car market. Many firms had gone bankrupt. Others had shifted to truck production and managed to survive.

World War II and the postwar years. Automobile manufacture in Europe was halted in 1939 by the outbreak of World War II (1939-1945). In this war, the Allies, who included Canada, the Soviet Union, and the United Kingdom, defeated the Axis powers, who included Germany and Japan. The United States entered the war on the side of the Allies in December 1941. In several countries, the automakers turned their production capacity to making war equipment. This equipment included not only military trucks, jeeps, and personnel carriers, but also tanks, aircraft and aircraft engines, ammunition, artillery, and marine engines.

Great changes occurred in the auto industry between

Early 1940's — Automakers turned to manufacturing military equipment during World War II.

1948 — Tubeless tires were introduced. Their casing was made airtight by an inner liner.

1954 — Hudson and Nash-Kelvinator combined to form American Motors Corporation (AMC).

1956 — The Highway Act called for building a system of interstate highways.

Motor Vehicle Manufacturers Association

Army tanks were produced by the automobile industry during World War II (1939-1945).

Motor Vehicle Manufacturers Association

The Studebaker represented the "new look" in automobiles after the end of World War II. Cars became longer, wider, and lower, like the 1947 model shown here.

Motor Vehicle Manufacturers Association

Freeway construction began full force with passage of the Highway Act of 1956. The act called for building 41,000 miles (66,000 kilometers) of interstate highways.

A Hummer is a large, sturdy vehicle designed to drive on rough terrain. It was originally developed for the United States Army.

Ford North American Fleet Operations

A Lincoln limousine is an American luxury car usually driven by a chauffeur. It has a roomy interior and a large engine.

Late 1950's — American cars became larger, heavier, and more loaded with options, such as automatic transmission.

1959 — Imported cars gained 10 percent of the U.S. auto market. U.S. automakers began introducing compact cars.

1964 — Ford introduced the Mustang, the first compact car to feature sporty styling.

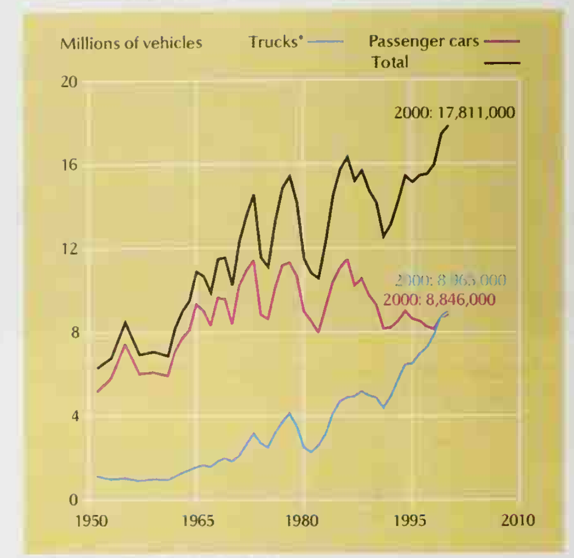
H. Armstrong Roberts

Large motor hotels sprang up along interstate highways during the 1950's. These conveniently located hotels catered to Americans on the go.

UPI/Bettmann

The West German Volkswagen Beetle arrived in great numbers in the United States beginning in the 1950's. It was a big hit with American consumers.

Motor Vehicle Manufacturers Association



The Ford Mustang, introduced in 1964, quickly became a favorite with car buyers. The Mustang was smaller and sportier than most other compacts.

the start of World War I and the end of World War II. There were far fewer manufacturers, but they could produce far more cars. Competition changed from simple mass production to broad marketing programs involving market research, product development, distribution, advertising, and publicity. Most of the industry giants had retired or died, and the companies tended to be run by corporate organization.

After the war, the auto industry resumed civilian production. The return of former servicemen and women, the enormous growth of the suburbs, and the unsatisfied demand for cars during the war all created a huge market for automakers. In 1949, the industry set a new production record for the first time since 1929. It set another record in 1950. During the 1950's, performance and styling became keys to selling. American cars and European luxury vehicles became longer, wider, and lower. Cheaper European cars grew shorter and narrower. Automatic transmission became available in low-priced cars. Engine power operated air conditioning, brakes, seats, steering, and the tops of convertibles.

The Big Three continued to control U.S. auto manufacturing. Several companies tried to enter the industry in the postwar years, but all failed by 1955. In 1954, two independent automakers, Hudson Motor Car Company and Nash-Kelvinator Corporation, formed American Motors Corporation (AMC). George W. Romney, head of AMC, strongly promoted the Rambler, the first successful small, or compact, U.S. car. In 1957, Ford brought out the Edsel. The company's market research had indicated high demand for a relatively expensive model. But during the time it took to bring the Edsel into production,

Car and truck sales in the United States since 1950

economic conditions and public taste changed. The vehicle was a financial failure.

By the late 1950's, imports—especially the West German Volkswagen Beetle—began to take a growing share of the U.S. market. Imports reached 10 percent in 1959. Sales of imports and of AMC's Ramblers persuaded the

1965 — Ralph Nader wrote *Unsafe at Any Speed,* which led to new safety regulations.

1968 — Devices that reduce exhaust fumes became standard equipment on U.S. cars.

1970's — A worldwide petroleum shortage helped make fuel-efficient cars popular.

1974 — A nationwide speed limit of 55 mph (89 kph) was established in the United States.

AP/Wide World

Front-seat shoulder belts became required equipment in automobiles in 1968. During the 1960's, car buyers began calling for such safety measures.

AP/Wide World

Imports from Japan gained a significant share of the U.S. auto market during the 1970's. Thousands of Japanese cars awaited delivery in Boston, *shown here.*

UPI/Bettmann

Long lines at filling stations were the result of a worldwide oil shortage in the 1970's. In Los Angeles, cars waited for a turn at the gas pump, *shown here.*

Sport utility vehicles, such as this Grand Cherokee by Jeep, became popular in the 1990's. These rugged vehicles are designed for rough terrain, but many people use them for everyday driving.

Chrysler Corporation

Big Three to enter the small-car market. In 1959, Ford brought out its compact Falcon, Chevrolet its Corvair, and Chrysler its Valiant. All the compacts sold fairly well.

By 1960, 77 percent of all U.S. families owned a car, and 15 percent owned two or more. Roads and highways began to look the same everywhere, bordered by motels, fast-food restaurants, filling stations, and shopping centers. About 10,000 miles (16,000 kilometers) of interstate expressways were in use. More than ever, the United States was a nation on wheels. In 1964, Ford introduced the Mustang, a smaller, sportier car than most compacts. Car buyers loved the Mustang at first sight.

The growth of government regulation. In 1965, an American lawyer named Ralph Nader wrote *Unsafe at Any Speed.* The book attacked Chevrolet's Corvair in particular and the auto industry in general for emphasizing profits and style over safety. Corvair sales plunged, and Chevrolet stopped producing the car in 1969.

The U.S. auto industry had operated largely free of government regulation. The situation changed in the 1960's, partly because criticism of the automobile had increased, especially after Nader's book appeared.

The United States was the first country to pass laws intended to lower pollution from cars. In 1965, the U.S. Congress passed the Motor Vehicle Air Pollution and Control Act, which amended the Clean Air Act of 1963. The new law ordered automakers to reduce the pollution produced by new cars. The Big Three complied by modifying the engine. The Clean Air Act of 1970 called for 90 percent reductions in tail pipe pollution. Auto-

1980 — Japan first surpassed the United States as the world's leading manufacturer of cars.

1980's — Japanese automakers built seven assembly plants in the United States.

1987 — The speed limit on rural U.S. interstates was allowed to rise to 65 mph (105 kph).

1995 — The 65 mph speed limit on rural U.S. interstates was abolished, allowing each state to set its own limit.

Chrysler Corporation

The minivan became popular during the 1980's. Its success provided a financial boost to Chrysler, which introduced the vehicle in 1984.

Nissan

Japanese auto plants in the United States, such as this Nissan plant in Smyrna, Tennessee, first appeared in the 1980's.

Aerodynamic designs, like this Miata by Mazda, presented one of the "hottest" new looks for automobiles in the early 1990's.

makers met this standard through engine improvements, the use of catalytic converters, and the change from gasoline containing the chemical *tetraethyl lead* to unleaded gasoline. Some countries still allow the use of gasoline with this additive. The Clean Air Act Amendment of 1990 required tail pipe pollution to be reduced by another 7 to 8 percent by 1997.

The 1966 National Traffic and Motor Vehicle Safety Act ordered certain changes to promote automobile safety. Car buyers' favorable response to the changes led automakers to provide safety measures that went beyond the law's requirements.

The rise of international automaking. During the 1960's, the auto industries of France, Italy, Spain, Sweden, and West Germany prospered. The Soviet Union and Italy agreed to produce Italian Fiat cars in the U.S.S.R. The Australian auto industry thrived, and Argentina and Brazil expanded production. Japan, however, made the most dramatic progress. Japanese production skyrocketed from about 50,000 cars in 1958 to more than 2 million by 1968.

A worldwide petroleum shortage during the 1970's resulted in high gasoline prices and long lines at filling stations. Many families with large automobiles switched to smaller, lightweight cars that were more fuel-efficient. In the United States, imported cars became popular because of their reputation for fuel efficiency. By 1980, imports had captured more than 25 percent of the U.S. market, and Japanese cars accounted for more than 80 percent of those sales.

During the middle and late 1900's, American automakers preferred to build plants abroad rather than export their cars. Exports of U.S. autos thus generally remained low. More than half of the cars American automakers exported went to Canada. In 1965, the United States and Canada agreed to the free movement of vehicles and parts between them. Thus, American automakers could closely adjust production at their many Canadian plants with operations at home.

American automakers began to sell imported cars themselves in the 1970's. Chrysler marketed cars made by the Japanese firm of Mitsubishi. Ford and General Motors retailed pickup trucks made by Japan's Toyo-Kogyo (now Mazda) and Isuzu, respectively. In 1978, Volkswagen began making cars in Pennsylvania. It became the first foreign automaker to produce vehicles in the United States since American Rolls-Royce of the United Kingdom closed its Massachusetts plant in 1931.

Challenges to the Big Three. The oil shortage led the U.S. Congress to pass a law in 1975 requiring manufacturers to make cars more fuel efficient. The 1974 cars averaged 14 miles per gallon (6 kilometers per liter) of gasoline. Under the new law, the 1985 models had to average 27 $\frac{1}{2}$ miles per gallon (11.7 kilometers per liter). The Big Three met the requirements by building lighter cars with smaller engines and by making mechanical improvements. Congress demanded even greater fuel efficiency in the 1990's.

The switch in consumer preference from large cars to small ones helped Japan surpass the United States as the world's largest automaker for the first time in 1980. The shiploads of imported cars pouring into the United States stunned the Big Three. The price of a new car rose sharply during the early 1980's. As a result, people kept their old cars longer before buying a new one.

Chrysler, in deep financial trouble, needed $1 $\frac{1}{2}$ billion in government-guaranteed private loans to survive. Lee Iacocca, head of Chrysler, turned the company around. Chrysler received the loans in 1980 and repaid them within three years. In 1984, Chrysler introduced a line of minivans that achieved huge success in the marketplace. In 1987, the company bought American Motors, which the French automaker Renault had largely controlled since 1977.

In 1981, the U.S. and Japanese governments placed voluntary restrictions on the export of Japanese cars to the United States. The restrictions encouraged Japanese carmakers to produce vehicles in the United States themselves. By the late 1990's, several Japanese manufacturers had assembly plants in the United States.

Light trucks and sturdy SUV's became increasingly popular in the United States. In the 1990's, U.S. production of such vehicles surpassed that of passenger cars.

The automobile today. About 450 million passenger cars travel the streets and roads of the world. Most cars are in the United States, Japan, Canada, and the countries of Western Europe. Many people of these nations consider a car a necessity. In most countries of Africa, Asia, Eastern Europe, and South America, the car is still regarded as a luxury by the great majority of the people.

The widespread use of the automobile has resulted in a number of challenges. Gasoline, the fuel that powers the engines of almost all cars, is a petroleum product. But most countries do not have a sufficient supply of oil to meet their energy needs. Also, cars give off harmful fumes that pollute the air. In addition, traffic accidents cause thousands of deaths and injuries each year.

Automakers and governments spend large sums of money seeking ways to reduce the hazards of driving. In the United States, the National Highway Traffic Safety Administration sets safety standards for new cars. To meet U.S. federal standards, car manufacturers must equip new cars with such safety features as safety belts, air bags, and shatterproof windows. Other required equipment includes a collapsible steering column and bumpers that can absorb the impact of collisions. Most other nations have strong safety regulations but require less safety equipment to be built into automobiles.

The United States imports far more goods than it exports. The U.S. auto industry accounts for much of the *trade deficit* because it exports relatively little, and yet the United States is the world's largest importer of cars. A large portion of the deficit results from trade with Japan, reflecting the many Japanese cars Americans buy and the parts imported for Japanese auto plants in the United States.

Cars of tomorrow will probably be increasingly fuel efficient and less polluting. Internal combustion engines will probably still power most automobiles. But worries about pollution will likely increase the use of vehicles that use alternative fuels, despite their limited range and speed. Delivery services and other commercial fleets in large cities will probably use such vehicles. *Hybrids,* vehicles that have all the components of electric cars plus another power source, may serve as a compromise between electrics and traditional automobiles. *Fuel cells,* devices that convert chemical energy to electrical energy, may be used in hybrids.

Toyota Motor Company

A hybrid, such as this Toyota Prius, combines a battery-driven electric motor with another power source—in this case, a gasoline engine—that charges the batteries and powers the motor.

Computerized controls will do more and more tasks in tomorrow's cars because of their low cost and precise functioning. With the flick of a switch, computerized suspension systems will adjust to changes in the road surface. Computers will also play an increasing role in creating tomorrow's cars, from the designing to the engineering to the assembling. The selling and servicing of cars will also be more and more computerized.

Many modern automobiles include an *on-board navigation system.* This electronic device uses a network of satellites called the Global Positioning System to locate a driver's vehicle. It can then display a map showing the best route to reach a specific destination selected by the driver. David J. Andrea and Michael S. Flynn

Automobile, Model, is a small-scale copy of a car. Many people enjoy making and collecting model cars as a hobby. Some hobbyists collect many different types of model cars. Others collect only cars from a certain period or specialize in models of racing cars, antique cars, or cars of historic value.

Some models are unique, handcrafted cars made of clay, wood, plastic, or plaster of Paris. But the most popular type of model is made of molded plastic and is sold as a kit. Because of modern advances in plastics molding, manufacturers can produce kits of very detailed models at a low cost. Many types of vehicles, including sports cars, trucks, racing cars, and unusual show cars,are available in model kits. The kits include step-by-step instructions on how to assemble the models and require such tools as pliers, a sharp knife, and a small drill. Popular kits include replicas of the stock cars used in such races as the Daytona 500. People can also collect die-cast metal models or plastic promotional models of current cars that can be obtained from car dealers.

Roy Ritola, Inc.

A model automobile may be a copy of a historic, modern, or imaginary car. This model is of a Mercedes-Benz 540, a version of the German car that was popular during the 1930's.

Some hobbyists have favorite models they build as *stock.* A stock car looks like the real car as it was produced at the factory. Others prefer to *customize* their cars. This means that they give them special touches or features, such as elaborate paint jobs, unusual decorations, or molded plastic wheels.

Some people enjoy the excitement of radio control (R/C) car racing. In the early years of radio control racing, the model cars used fuel-powered model airplane engines. Now most radio control cars are powered by a battery-operated electric motor. The motor drives the wheels through a set of gears. A carefully tuned transmitter controls the car's speed and steering. The transmitter sends radio signals to a receiver built into the car.

In racing, each participant has an assigned channel or frequency that prevents cars from receiving conflicting signals from other competitors' transmitters. Most R/C car races last 8 or 10 minutes. The car that finishes the most laps on a track during the time limit wins the race.

Some model car hobbyists enter the Pinewood Derby. Pinewood Derby cars are wooden blocks that can be shaped to look like racing or passenger cars. The races are held on downhill ramps. Winners in a series of races compete with other winners until the car that finishes first in the final race is named champion. Participants in the derby can also win prizes for the best-designed car, for superior workmanship, or for the most original car.

Radio control model cars are operated by radio signals transmitted to long, thin antennas attached to the car's hood, *left.* At the start of a road race, *right,* operators prepare to guide their cars with radio signals they send from handheld transmitters.

Focus on Sports

Stock cars whip around a turn during the annual Daytona 500 race in Daytona Beach, Florida. Stock car racing is the most popular kind of automobile racing in the United States.

Automobile racing

Automobile racing is a thrilling sport that tests the speed and performance of automobiles and the skill and daring of drivers. Each year, millions of spectators around the world attend a wide variety of automobile races. One of the most famous is the Indianapolis 500, which attracts hundreds of thousands of people yearly.

Much of automobile racing's popularity lies in the great variety of racing cars and racing events. The vehicles range in size from small, open karts (formerly called *go-karts)* to large sedans. However, all racing cars can be divided into two major groups: (1) production cars and (2) cars built specifically for racing. Production cars are factory-made passenger cars converted into racing cars. Most cars built only for racing are not designed to carry passengers. Automobile races range from $\frac{1}{4}$ mile (0.4-kilometer) *drag races* that last only seconds to *rallies* that may cover great distances and last weeks.

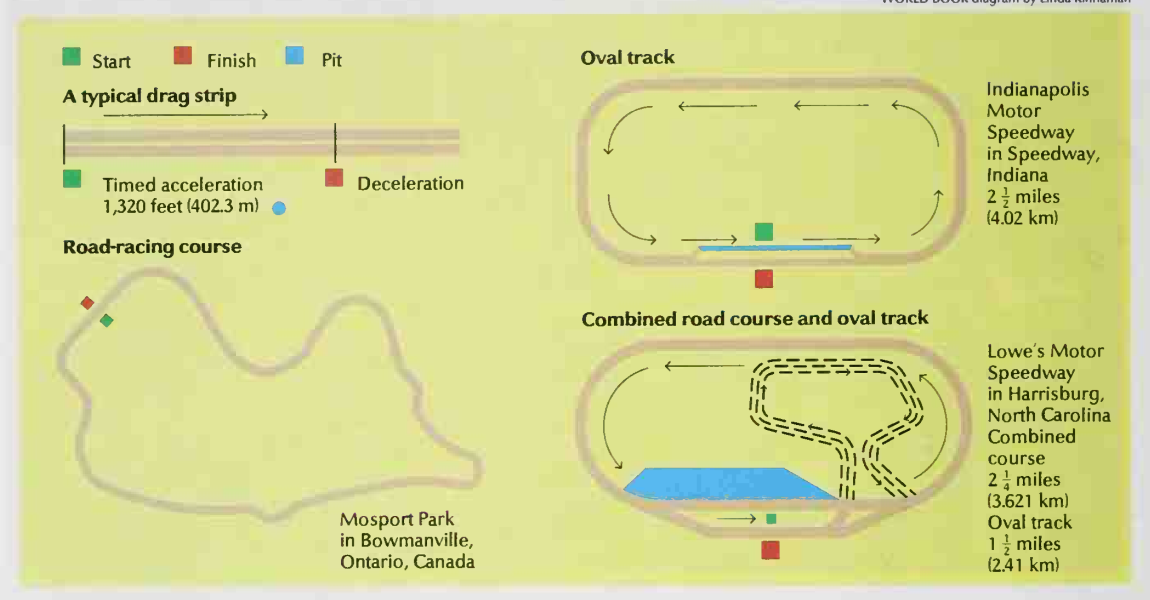
There are two major types of racing tracks, *oval tracks* and *road-racing courses.* Oval tracks vary from less than $\frac{1}{5}$ mile (0.3 kilometer) to more than 2 $\frac{2}{3}$ miles (4.2 kilometers) long. They have straightaways and banked turns. Most oval tracks have an asphalt surface, but some have a dirt surface.

Road-racing courses resemble country roads. They have straightaways, hills, and a variety of turns. Many turns are described by their names, such as *hairpin, dogleg,* and *ess.* Some courses include sections of public roads or are combined with oval tracks. Races are faster on big oval tracks than on road courses because cars can maintain higher speeds on banked turns than on sharp, irregularly shaped turns. Road courses in the United States range from less than 2 miles (3.2 kilometers) to almost 5 miles (8 kilometers) long.

Events called *street races* have become increasingly popular in automobile racing. Such a race is run on a temporary course on city streets. The most famous street race is the one held annually in Monaco. Street races have also been held in such cities as Detroit; Long Beach, California; and Toronto.

Alongside both oval tracks and road-racing courses are special areas called *pits,* where drivers make servicing stops and refueling stops during a race. In the pits, a skilled crew changes tires and may make minor adjustments and repairs. The pit stops often take only seconds to complete. A delay in the pits can lose the race for a driver. Pit crews are part of large professional racing teams. Such teams also include car designers, builders, mechanics, and timekeepers, as well as the car owners and the drivers themselves.

Safety measures



Automobile racing is a highly dangerous sport, but many steps have been taken over the years to make it as safe as possible for both spectators and drivers. Strong guardrails and heavy fencing protect spectators from cars that have gone out of control. A driver's most important piece of safety gear is a racing helmet. Such a helmet has a hard outer shell made of fiberglass or

Sylvia Wilkinson, the contributor of this article, is the author of numerous books on automobile racing, including the series World of Racing *and a history of stock car racing,* Dirt Tracks to Glory.

Kinds of automobile racing courses and tracks

Most races are held on *oval tracks* or *road-racing courses.* Oval tracks have fast-banked turns. Road-racing courses have some sharp turns. On a combined road course and oval track, races may be run on the combined course or only the oval track. *Drag strips* are straight.

WORLD BOOK diagram by Linda Kinnaman

carbon fiber and a foam-cushioned, flame-resistant lining. Drivers also wear flame-resistant clothing from head to toe. Some race car drivers also wear a special protective face mask.

Lap and shoulder belts are standard safety equipment on racing cars. A device known as the HANS (*h*ead *a*nd *n*eck *s*upport) reduces the chance of serious injury caused by the violent movement of a driver's unrestrained head and helmet. Every car also has a built-in structure to help protect a driver's upper body if the car rolls over. A racing car with an *open cockpit*—that is, without a roof—has a *roll bar,* a dome-shaped metal bar that arches over the driver's head. A car with a roof has a *roll cage,* a structure of steel tubes that prevents the roof of an overturned car from collapsing.

A racing car carries fuel in a leak-resistant *fuel cell* within a metal or plastic fuel tank. A fuel cell consists of a strong, rubberlike bladder usually filled with a spongy material or foam that absorbs the fuel and helps keep it from spraying in case of a crash. The fuel cell foam also prevents fuel from sloshing around in the tank during a race, which makes a car harder to control.

Many race sites have medical facilities to provide emergency treatment to injured drivers in the event of a crash. In some cases, helicopters are available to rush injured drivers to nearby hospitals.

Sponsorship

The cost of building or buying a racing car and keeping it in top condition makes automobile racing one of the most expensive sports. For this reason, most professional racing teams have sponsors. A sponsor may be a wealthy person or a manufacturing company, such as an automobile maker or a household products company.

In return for their financial support, manufacturers advertise their products on the racing cars and on the uniforms of the drivers and crews. Television coverage of races also gives sponsors exposure.

Racing organizations

The Fédération Internationale de l'Automobile (FIA) regulates organized automobile racing in about 90 countries throughout the world. The United States has five national racing organizations represented in the FIA. They are the National Association for Stock Car Auto Racing (NASCAR), Professional Sports Car Racing, Inc. (SPORTS CAR), the United States Auto Club (USAC), the Sports Car Club of America (SCCA), and the National Hot Rod Association (NHRA).

Two other major American racing organizations are Championship Auto Racing Teams (CART) and the Indy Racing League (IRL). These groups plan and supervise certain kinds of races. Each group establishes *classes* (divisions) of races for the type of racing it governs and specifies the cars in a class. Canada is represented in the FIA by the Canadian Automobile Sports Club (CASC).

Kinds of automobile racing

There are five major kinds of automobile racing: (1) Formula One racing, (2) sports car racing, (3) Indy car racing, (4) stock car racing, and (5) drag racing.

Formula One racing features the most expensive racing cars. Each Formula One car is designed and manufactured individually. The cars are built according to a *formula* (set of specifications) drawn up by the FIA. The formula dictates tire configuration and chassis and engine limits as well as the car's aerodynamics. Formula One cars are also called *Grand Prix* (pronounced *grahn PREE)* cars. The French term *Grand Prix* is the name of the race series in which the cars compete.

Formula One cars are designed on some of the same principles as airplanes. Like the *fuselage* (body) of an air-

plane, a Formula One car has a *monocoque* construction. In this type of construction, the car's central structure is a tube-shaped shell made of aluminum, carbon fiber, or other durable, lightweight material. This structure, sometimes called the *tub*, provides the connecting point for the engine, suspension system, and other parts of the car and bears the mechanical stresses. A Formula One car has front and rear wings. The flow of air over and under the wings produces a downward force that presses the car to the ground. This *downforce* holds the car to the road, which enables it to go faster through turns. Formula One cars have only one seat, an open cockpit, and *open wheels*—that is, no fenders. The engine of a Formula One car is in the rear.

Grand Prix races are the most famous international series of racing events held on road courses. The series consists of about 15 races held in several countries, including Canada, France, and Monaco. The races are governed by the FIA representative in each country. In the United States, the representative is the Automobile Competition Committee for the United States (ACCUS). ACCUS, in turn, authorizes the SCCA to organize U.S. Grand Prix events. In Canada, the races are governed by the CASC.

Grand Prix races are held on exceptionally challenging courses. The races range from about 150 to 200 miles (240 to 320 kilometers) long. Cars reach speeds of more than 200 miles (320 kilometers) per hour on straightaways and may go as slow as 30 miles (48 kilometers) per hour around sharp turns. The first driver to finish the required number of laps around the course wins. The top six drivers receive points. The driver who earns the most points in Grand Prix races in a year wins the World Drivers' Championship.

Sports car racing consists of events for both production sports cars and specially built *sports-racing cars.* Most sports car races are held on road courses or on combined road courses and oval tracks. The SCCA governs a major series of races for sports cars—the Trans-American (Trans-Am) Championship. Sports cars are also driven in endurance races sanctioned by the SCCA and SPORTS CAR.

The Trans-Am Championship consists of a series of road races in the United States and Canada. The races feature top American sports sedans manufactured by Ford Motor Company, General Motors Corporation, and Chrysler Corporation, such as the Camaro and the Mustang.

A Trans-Am car has the same shape as the original production model and retains such features as doors, fenders, and windshield. However, cars resemble only the shape of a namesake and are built on a special racing framework. The Trans-Am series uses a *power-to-weight formula* to help make the races more competitive. According to the formula, cars with less potential horsepower may weigh less than cars with more powerful engines.

The Trans-Am series involves about 14 to 16 races. Each race is approximately 100 miles (160 kilometers) long. The top finishers in each race earn points. The driver who earns the most points becomes the Trans-Am champion.

Endurance races are among the most popular sports car events. Such races last from less than 3 to 24 hours.

Thomas Zimmermann, FPG

Formula One racing features cars with one seat, a rear engine, and front and rear wings. They have no roof or fenders. The wings produce a *downforce* that presses the cars to the ground.

The winner is the driver who completes the most laps within the specified time or becomes the first to cover the required distance. During an endurance race, cars make regular pit stops to refuel, change tires, and alternate drivers. Two or three drivers usually take turns driving the car during the race. Famous endurance races include the 24-hour events held in Daytona Beach, Florida, and Le Mans, France.

Some endurance cars have *turbocharged* engines. Turbocharging increases the power of a small engine by using the energy from the engine's exhaust gases to spin a windmill-like pump. The pump forces a large volume of a fuel and air mixture into the engine's *combustion chamber,* where the mixture is burned. The greater the volume of the fuel-air mixture in the combustion chamber, the more power is released and the more energy is converted into the car's speed.

Indy car racing. Indy cars, named after the Indianapolis 500, resemble Formula One cars. They have one seat, an open cockpit, open wheels, and a monocoque chassis that serves as a frame structure and body. To provide downforce, an Indy car has front and rear wings plus two structures called *sidepods,* one on each side of the cockpit. Each sidepod has a curved *ground-*

P. Boisvert, FPG

Endurance races are among the most popular sports car events. They may last from 3 to 24 hours. A famous endurance race is the 24-hour event held in Daytona Beach, Florida.

Sports-car racing is popular in the United States and Canada. The cars are built especially for automobile racing. They race on road courses or on combined road courses and oval tracks.

Focus on Sports

During a pit stop at the Indianapolis 500, crew members refuel a car and change its tires. Pit stops must be made in seconds. A delay in the pits can lose the race for a driver.

effects panel on its underside. The ground-effects panels direct the flow of air moving under the car so that a low-pressure area, or partial vacuum, is created beneath the car. The resulting suction helps hold the car to the track.

Indy cars have turbocharged engines that burn a form of alcohol called *methanol.* Methanol provides maximum horsepower without overheating the engine. In addition, methanol does not ignite as easily as gasoline, reducing the risk of fire in case of a crash. Indy car races are held on oval asphalt tracks, such as the California Speedway in Fontana, California, and on road courses, such as Road America in Elkhart Lake, Wisconsin. Races range from 150 to 500 miles (240 to 805 kilometers) long. Indy cars can average more than 200 miles (320 kilometers) per hour on oval tracks.

The Indianapolis 500 is the most famous race for Indy cars. It takes place on the 2 $\frac{1}{2}$-mile (4.02-kilometer) Indianapolis Motor Speedway in Speedway, Indiana. There are 33 starting positions. Drivers with the highest average speeds in four qualifying laps earn the chance to race. The first driver to complete 200 laps around the track—a distance of 500 miles (805 kilometers)—wins the race. All the participants share in the largest *purse* (amount of prize money) in automobile racing, which has exceeded $7,500,000. First prize has reached more than $1 million.

Indy car racing is controlled by CART and the IRL. The Indianapolis 500 is governed by USAC, which is aligned with the IRL. The IRL runs only on oval tracks, while CART sanctions races on oval tracks and on road courses.

Stock car racing is the most popular kind of automobile racing in the United States, especially in the South, where the races originated. Stock car racing is the only major form of track racing that has always been restricted to American-made automobiles. The chief stock car races are restricted to large, late-model sedans like those car dealers have in stock. The cars are specially built for racing, but from a distance they retain the look of ordinary passenger cars. They have an engine mounted in the front, fenders, doors, and a windshield. Drivers sit in the usual upright position. Stock cars have steel bodies and are therefore much heavier than other kinds of racing cars. Stock cars that are raced in the Winston Cup series have a minimum weight of 3,500 pounds (1,420 kilograms), compared with about 1,500 pounds (680 kilograms) for an Indy car. However, a stock car's large, powerful engine enables it to reach speeds of 200 miles (320 kilometers) per hour.

Most major stock car races are held on oval asphalt tracks. The distance around the tracks ranges from about $\frac{5}{8}$ mile (0.8 kilometer) to 2 $\frac{2}{3}$ miles (4.2 kilometers) for *superspeedways,* such as the one in Talladega, Alabama. A superspeedway has wide, high-banked turns that enable cars to make the turns at speeds up to 200 miles (320 kilometers) per hour.

Nearly all stock car races are held in the United States. NASCAR governs U.S. competition, including the Winston Cup series. Winston Cup races range from about 215 to 600 miles (345 to 965 kilometers). Highlights of this series of about 30 races include the Daytona 500 in Daytona Beach; the Southern 500 in Darlington, South Carolina; the Winston 500 in Talladega; and the Brickyard 400 at Indianapolis Motor Speedway.

Drag racing. A drag race is a high-speed event held on a straight paved track called a *drag strip.* Drag races are $\frac{1}{4}$ mile (0.4 kilometer) long, and some cars cross the finish line in less than five seconds. The fastest cars reach speeds of more than 300 miles (480 kilometers) per hour. Such cars use a parachute at the rear to slow down the car.

Drag-racing cars range from mass-produced passenger cars to strange-looking models built for racing only. The three types of professional drag-racing cars are (1) Pro Stock cars; (2) Top Fuel cars; and (3) Funny Cars. Pro Stock cars are especially built for racing but are required to resemble production cars. A Pro Stock car burns gasoline and must use the car manufacturer's engine. For example, a Ford body must use a Ford engine. Top Fuel cars, also called *dragsters,* and Funny Cars burn a mixture of nitromethane and alcohol. Top Fuel cars may be built in any way the designer wishes. All of the cars have a rear engine, one seat, and a long, slender frame. They have large rear tires to apply more than 6,000 horsepower to the road. The front wheels on Top Fuel cars are narrow like bicycle wheels to reduce drag. Funny Cars must have a fiberglass copy of a passenger car body and meet restrictions on the *wheelbase* (distance between front and rear axles).

Hundreds of dragsters may race in a *drag meet.* The cars race two at a time, accelerating from a standing start. The losing car is eliminated from the competition,

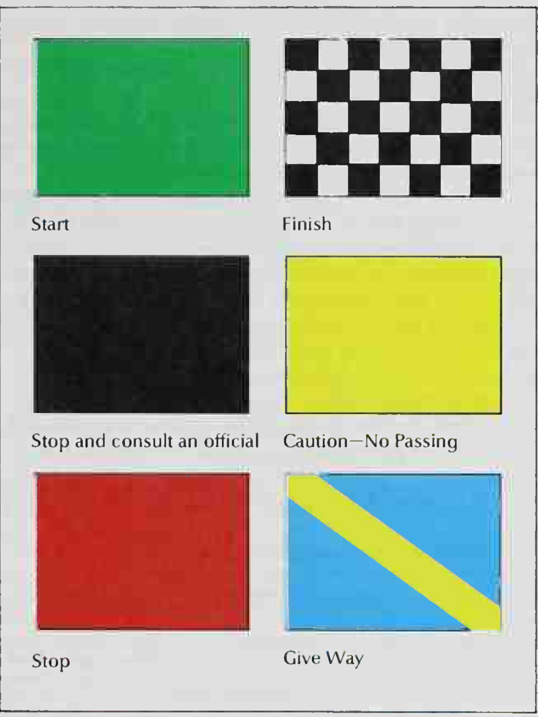
and the winner advances in the competition to race against another car. The elimination continues until only two cars are left. The winner of the last round is the meet champion.

The NHRA supervises the major drag races in the United States and Canada. Each year, it conducts more than 50 championship races in which the drivers earn points toward the Winston Drag Racing Championship. Important races in the series include the Gator Nationals in Gainesville, Florida; the U.S. Nationals in Indianapolis; and the Winternationals in Pomona, California.

Other kinds of racing. *Sprint cars* are open cockpit cars that race mainly on dirt oval tracks. The cars have powerful front engines and open wheels. They often have large wings mounted on the roll cage for better downforce.

Midgets are smaller than sprint cars. They have highly modified small engines in the front that produce more than 300 horsepower. Midget tracks are usually $\frac{1}{5}$ mile (0.3 kilometer) to $\frac{1}{2}$ mile (0.8 kilometer) in length. Most races last 30 laps.

The *quarter midget* is a popular small racing car. It has an open cockpit and open wheel with the engine in the front. Many successful drivers raced quarter midgets while still in elementary school.



A *kart* is the smallest racing vehicle. Many race drivers begin their careers in karting. Children as young as 8 years old, as well as adults, compete in kart races, which are generally held on miniature road racing tracks. See **Kart racing.**

A *Formula Atlantic* looks like a small Formula One or Indy car. The car has front and rear wings and a Toyota engine. Formula Atlantics race on oval asphalt tracks and on road-racing courses. They can go as fast as 160 miles (260 kilometers) per hour. Formula Atlantic racing is popular in the United States as a stepping stone for young drivers who hope to move up to Formula One or Indy car racing.

Two rugged forms of racing are *off-road races* and *rallies*. Popular vehicles for off-road races include small trucks produced by such manufacturers as Nissan, Toyota, and Mazda. Most off-road races are long-distance events run on rough, desert terrain.

Most rally cars are production models, some of which have four-wheel drive. The chief kinds of rallies are *road rallies* and *pro-rallies*. Road rallies are held on public roads and feature some of the longest automobile races. Pro-rallies are held on rugged back roads. The SCCA governs the major U.S. rallies.

The world's fastest cars are jet-powered vehicles. These cars do not race against other cars but against the clock to break the world land speed record. Most speed trials consist of two 1-mile (1.6-kilometer) runs on the hard, level surface of the Bonneville Salt Flats in Utah.

WORLD BOOK illustrations

Automobile-racing flags signal the start and finish of a race. During a race, other flags tell drivers to talk to an official, to drive with caution and not to pass because of an accident on the course, to stop, or to give way to a faster car.

National Hot Rod Association

In a drag race, two cars at a time compete against each other, accelerating from a standing start. The fastest drag cars can travel more than 300 miles (483 kilometers) per hour.

History

The sport of automobile racing began in the 1890's. The first races were run on *open-road courses*, which consisted of public roads between towns. Many of the courses were hilly, sharply winding dirt roads. Drivers often lost control of their cars and crashed, sometimes injuring spectators standing along the road.

Growth of organized automobile racing. The world's first automobile-racing organization, the Automobile Club de France, was established in 1895. Later that year, it supervised the first actual automobile race—a 732-mile (1,178-kilometer) round trip between Paris and Bordeaux, France. Twenty-two drivers started in the race, but only nine finished. The winners averaged 15 miles (24 kilometers) per hour. That same year in the United States, J. Frank Duryea, a pioneer automobile maker, beat five other drivers in a race from downtown Chicago to the suburb of Evanston and back.

The most famous open-road races in the United

States, the Vanderbilt Cup races, began on Long Island in New York in 1904. But the crowds along the road were difficult to control, and so the races were held in several other places around the country after 1910. In 1916, the races were discontinued. In time, more and more races in Europe and the United States were run on tracks designed specifically for automobile racing.

The first Grand Prix race took place on a large course near Le Mans, France, in 1906. It was supervised by the Fédération Internationale de l'Automobile (FIA), which was established in 1904 to govern international automobile racing. The Indianapolis Motor Speedway opened in 1909, and the first Indianapolis 500 was run in 1911. The Grand Prix series began in 1920. The first 24-hour endurance race for sports cars was held in Le Mans in 1923. Organized stock car racing began in 1936 in Daytona Beach. The first Grand National (now Winston Cup) race for stock cars took place in Charlotte, North Carolina, in 1949. In 1950, the FIA established the World Drivers' Championship for Grand Prix drivers.

Development of racing cars. The earliest racing cars were simply the first automobiles. These heavy, open vehicles had poor brakes and were hard to steer. The main way to increase a car's power for racing was to make its engine bigger. However, technological advances during World War I (1914-1918) enabled car designers to produce more power from a smaller engine. Racing cars thus became trimmer and faster in the 1920's and 1930's. Competition among carmakers also hastened the development of racing cars.

The major automobile races were canceled during World War II (1939-1945). After the war, racing cars became faster than ever. The development of the rear-engined racing car in the mid-1950's revolutionized the sport. It enabled drivers to lean back and so conform to a car's streamlined body. Placing the engine behind the driver also improved the car's weight distribution and provided better traction. By the early 1960's, rear-engined vehicles had almost completely replaced front-engined cars in racing. In 1962, Colin Chapman, an

English racing car designer, introduced the monocoque construction to Formula One cars. Wings appeared on racing cars in the mid-1960's. In 1978, Chapman introduced the Lotus 79 ground-effects car.

Automobile racing today. Racing car designers are constantly seeking ways to make cars run faster. At the same time, some racing organizations are changing their rules for safety reasons. In the early 1980's, for example, Grand Prix teams approved rule changes that banned ground-effects skirts on Formula One cars.

Outstanding drivers of the 1990's and early 2000's included Jacques Villeneuve of Canada, Michael Schumacher of Germany, Damon Hill of the United Kingdom, Emerson Fittipaldi of Brazil, Arie Luyendyk of the Netherlands, and U.S. drivers Michael Andretti and Al Unser, Jr. (the sons of drivers Mario Andretti and Al Unser, Sr.), Dale Earnhardt, Jeff Gordon, Dale Jarrett, Tom Kendall, Butch Leitzinger, and Alex Zanardi.

Several women have also achieved success in automobile racing. In 1977, Janet Guthrie of the United States became the first woman to race in the Indianapolis 500. Guthrie placed ninth in the race in 1978. Shirley Muldowney, an American drag racer, won the Top Fuel Winston World Championship three times—in 1977, 1980, and 1982.

In the mid-1990's, a split developed between owners and executives in Indy car racing. The result of the split was the formation of the IRL as a rival to CART.

Autopsy, *AW tahp see,* is an external and internal examination of the dead. It is also called *necropsy* and *post mortem examination.* The law requires that every cause of death be verified by a physician or by a coroner's jury. If the physician knows that death is from natural causes, he or she signs the death certificate and no autopsy need be performed. If uncertain of the conditions leading to the cause, however, the physician may ask for an autopsy for scientific reasons. A medical examiner or coroner may legally insist on an autopsy when death results from suicide, homicide, or unknown causes. See also Medical examiner. John I. Thornton

Autry, Gene (1907-1998), became famous for his roles as a singing cowboy in Western films from the 1930's through the early 1950's. He later became a successful business executive.

Orvon Gene Autry was born in Tioga, Texas, near Pilot Point. He began recording cowboy songs in 1929 and made his first hit record, "That Silver-Haired Daddy of Mine," in 1931. Autry wrote over 250 songs, including such hits as "Tears on My Pillow" (1941) and "Here Comes Santa Claus" (1947). He also made popular recordings of "Back in the Saddle Again" (1939), "Rudolph the Red-Nosed Reindeer" (1949), "Frosty the Snowman" (1950), and "Peter Cottontail" (1950).

In 1934, Autry moved to Hollywood, Calif., to appear in motion pictures, and he made his first film that same year. He acted in more than 100 Western movies and also continued to perform as a singer. During the 1950's, Autry began a successful business career. In 1960, he became an owner of the Los Angeles (now California) Angels baseball team, which played its first season in 1961. Lee Rector

Autumn is the season between summer and winter. The Northern Hemisphere, the northern half of the earth, has autumn weather during late September, October, and November. Autumn weather does not last so long in the polar region, where extremely cold winter weather begins earlier. In tropical regions, seasonal changes are not great. The Southern Hemisphere has autumn from March until early June. For the dates of the first day of autumn and information about the position of the earth and sun during autumn, see **Season**.

Many people call this season *fall* because it is the period of falling leaves. Autumn is also harvest time for many crops. In North America, early autumn days are generally warm and nights are cool. As winter approaches, the air becomes chillier and frost often occurs at night. In much of North America, the end of autumn is marked by the freezing of lakes and streams, southern migration of birds, and prewinter snowstorms.

Autumn—especially September—is the season when most hurricanes occur. Hurricanes cause great damage along the coasts of the Gulf of Mexico and the western North Atlantic Ocean. John E. Kutzbach

Autumnal equinox. See **Equinox.**

Auxin, *AWK sihn,* is the name of a group of hormones that help control plant growth. Plant embryos, young leaves, and the tips of stems and roots produce auxins that influence the growth of different parts of plants. Auxins play an important role in plant *tropisms* (bending movements). For example, the stems or leaves of many plants bend toward light. Such movement, called *positive phototropism,* occurs because auxins accumulate on the dark side of the stem or leaf stalk, causing the cells on that side to lengthen. This elongation gradually bends the stem or leaf toward the light.

It is almost impossible to extract large amounts of auxins from plants. Artificially produced auxins are widely used in weedkillers. They are also used to promote root formation on plant cuttings, to stimulate the growth of seedless fruits, and to prevent sprouting in stored potatoes and onions. Joseph E. Armstrong

See also **Hormone** (Plant hormones); **Tropism.**

Ava. See **Kava.**

Avalanche is a mass of snow that slides down a mountain slope. Most avalanches result from weather conditions that cause snow on a mountain slope to become unstable. Such disturbances as heavy winds, earth tremors, and explosions can send the snow sliding down the mountain. Skiers have started many avalanches.

There are three chief kinds of avalanches. A *dry snow avalanche* consists of powdery snow and air that may move faster than 100 miles (160 kilometers) per hour. A *wet snow avalanche* is a mass of wet, dense snow that typically moves slower than a dry snow avalanche. In a *slab avalanche,* a solid portion of snow breaks loose as a slab and splits into pieces as it slides.

Experts can often recognize the conditions that lead to avalanches by studying the terrain, snow, and weather in an area. To help control avalanches, they use explosives to reduce snow build-up. They also replant trees on slopes, and erect barriers. H. J. McPherson

Avant-garde, *AH vahn GAHRD,* is a term commonly used to describe people in any field who break with tradition and conventional standards in their work. The term is especially used to describe movements in the arts. Avant-garde artists emphasize experimental and original methods and oppose accepted ways of doing things. They sometimes attack past and present attitudes about art in the interest of creating a better future.

Avant-garde was originally a French military term, meaning an advance guard that preceded the main body of troops. The term was first used in its current meaning by the French socialist leader Henri de Saint-Simon in 1825. During the 1800's, most avant-garde art was used to promote social reform. But in the late 1800's, a period of relative political stability, a doctrine of "art for art's sake" developed. It emphasized the form of art itself, regardless of its effect on society.

Events of World War I (1914-1918) led to the reappearance of reform-based avant-garde art. These works criticized European culture and contributed to political and social reform movements after the war. But some artists in the early 1900's wanted to restore to art its primary creative function. For example, German artist Kurt Schwitters created collages from fragments of newsprint and discarded items, including stamps, wood, buttons, and cloth. He also wanted to weaken the authority of conventional art forms. Avant-garde ideals became especially important in art of the mid-1900's when artists tended to combine distinct art forms, such as architecture, motion pictures, music, painting, sculpture, and theater. Stephen C. Foster

Average is a number that is typical of a group of numbers. People usually think of an average as a *mean.* A mean is the sum of a group of numbers divided by the number of numbers. For example, the average, or mean, of 4, 5, 6, 7, and 8 is 6, or 30 divided by 5. Other numbers are also typical of a group of numbers. A *median* is the middle number of a series of numbers arranged in numerical order, if there is an odd number of numbers. If the number of numbers is even, the median is the mean of the middle two numbers. A *mode* is the number that occurs most often in a group. See also **Mean; Median; Mode; Statistics** (Probability).

Averroës, *uh VEHR oh eez* (1126-1198), was an Arabian philosopher. He was also known as Ibn Roshd (pronounced *ihb uhn ROOSHT*). Averroës was a devoted student of the writings of the Greek philosopher Aristotle. His interpretations of Aristotle were influential for many years. But Averroës' insistence on the eternity of matter and his denial of personal immortality were condemned by church authorities in the West. Because they wished to reconcile Aristotle's philosophy with Christian theology, the authorities argued that on these points Averroës was mistaken about Aristotle's position. Averroës was born in Córdoba, Spain. S. Marc Cohen

The Boeing Company

Modern airplane factories are a vital part of the aviation industry, which also includes airline and airport operations. This Boeing Company plant near Everett, Washington, produces Boeing 747, 767, and 777 jumbo jets, some of which are lined up awaiting delivery to major passenger airlines.

Aviation

Aviation is a term that includes all the activities involved in building and flying aircraft, especially airplanes. The first successful airplane flights did not take place until 1903. Yet today, airplanes affect the lives of people almost everywhere. Giant airliners carry passengers and cargo between the world's major cities in a matter of hours. Planes and helicopters rush medicine and other supplies to the farthest islands and deepest jungles. Farmers use airplanes to seed fields, count livestock, and spray crops. Aviation has also changed the way nations make war. Modern warfare depends on the instant striking power of jet fighters and bombers and the rapid supply capabilities of jet transports. Helicopters and other special aircraft are also important in military aviation.

Roger E. Bilstein, the contributor of this article, is Professor of History at the University of Houston-Clear Lake, and the author of several books on aviation, including Flight in America: From the Wrights to the Astronauts.

Hundreds of thousands of airplanes are used throughout the world. They range from small planes with room for only a pilot to enormous jumbo jets, which can carry hundreds of passengers. To produce and operate all these airplanes requires the skills of millions of workers in many countries—from the engineers who design the planes to the mechanics and pilots who service and fly them. Many government agencies also work to make flying safer and more dependable. All these activities together make up the *aviation industry.* The industry's two major activities are (1) the manufacture of aircraft and aircraft components, such as engines, and (2) the operation of airlines. The manufacture of aircraft, together with the manufacture of spacecraft, missiles, and related electronic equipment, is often called the *aerospace industry.*

The aviation industry began on Dec. 17, 1903, near Kit-

ty Hawk, North Carolina. That day, Orville and Wilbur Wright—two brothers who operated a bicycle-manufacturing shop in Dayton, Ohio—made the world's first successful piloted airplane flights. They had built their airplane after studying the writings of other aviation pioneers and after experimenting with gliders, kites, and wind tunnels.

Within a few years, several small factories in Europe and the United States were producing airplanes. Daredevil fliers bought many of these planes and used them to put on thrilling air shows. The governments of various countries also began to buy airplanes to build small air forces. The daring feats of the early fliers and the development of military airplanes greatly encouraged the growth of the aviation industry.

By the late 1930's, airplanes had become an important means of transportation. Then, in the 1950's, engineers developed jet airliners—and air travel grew at an even faster rate. In 1960, the world's airlines carried about 100 million passengers. By the early 2000's, they carried about 1 $\frac{1}{2}$ billion people annually.

Almost from the beginning of the aviation industry, the governments of most nations have been deeply involved in its activities. Airplanes have such great importance as weapons of war that many countries have encouraged and financed improvements in airplane design for military reasons. Most nations have also supported the development of *civil aviation* (the operation of nonmilitary aircraft).

Although aviation includes all types of heavier-than-air craft, this article deals chiefly with airplanes. To learn about the two other main types of heavier-than-air craft, see **Glider** and **Helicopter**. The **Airplane** article traces the history of human efforts to fly and the development of the airplane. It also describes how a plane flies, how pilots navigate, and how planes are built. For a discussion of space flight, see **Space exploration**.

The aviation industry

The aviation industry can be divided into five branches: (1) aircraft manufacturing, (2) general aviation activities, (3) airline operations, (4) airport operations, and (5) aviation support industries.

Aircraft manufacturing. Aircraft companies produce chiefly airplanes, but many also manufacture gliders, helicopters, and parts for spacecraft. Some parts factories and assembly plants are owned by *conglomerates,* enormous corporations that control a number of firms in largely unrelated fields. Most of the aircraft used around the world are manufactured in the United States.

The Russian aerospace industry produces aircraft and equipment for use throughout the former Eastern bloc—that is, the former Soviet Union and its Eastern European allies. Russia also exports military aircraft to many other countries. British Aerospace is the United Kingdom's major manufacturer of aircraft. Europe's other leading aircraft manufacturing countries are France, Germany, Italy, and Spain. Other countries with important aerospace industries include Brazil, Canada, China, India, Israel, Japan, and South Africa. Many other nations have facilities for aircraft repair and maintenance.

Manufacturers produce three main types of airplanes: (1) general aviation planes, (2) commercial transport planes, and (3) military planes. General aviation activities range from business and personal flying to rescue services. Most general aviation planes are small propeller driven airplanes with one or two engines. Many businesses use jets. Commercial transport planes are large airplanes used to carry both passengers and cargo or cargo only. Airlines operate these planes. The smallest commercial transports carry from 20 to 100 passengers, and the largest, called *jumbo jets* or *airbuses,* carry several hundred. Most commercial transports are jet planes with two, three, or four engines. Military planes include bombers, fighters, and military transports owned by the governments of various countries and operated by their armed forces. See **Airplane** (Types of airplanes).

In some countries, the government wholly or partly owns some or all aircraft companies. All aircraft companies in the United States and some other countries are privately owned. But many depend heavily on government orders for military planes, engines, missiles, or spacecraft. Many U.S. manufacturers—such as the Boeing Company, General Electric Company, and the Lockheed Martin, Northrop Grumman, and United Technologies corporations—receive large government contracts.

A modern jet airliner costs millions of dollars to build. A small company cannot afford to build such a plane, and even large companies often have trouble acquiring the necessary funds. Many companies have *merged* (combined) to cut costs. These mergers have produced some of the world's largest aerospace companies, including Boeing, British Aerospace, and the European Aeronautic Defence and Space Company.

A number of European nations have cooperated in special aircraft-manufacturing projects. For example, the British and French governments formed a partnership called a *consortium* to share the cost of building a supersonic transport (SST), the Concorde. An SST was designed to carry passengers at speeds faster than that of sound (see **Airplane** [Supersonic airplanes]).

General aviation activities include pleasure flying, land surveying, giving flying instructions, inspecting telephone lines, scattering seed, and spraying crops. Another important general aviation activity is using light planes to provide transportation. Most *air taxi services,* also called *commuter airlines,* use compact, twin-engine planes to carry passengers—usually fewer than 20—on short flights. They serve small communities and provide connecting flights to large airports. Some air taxi services have planes large enough to carry more than 20 passengers. Some large airlines also provide air taxi service.

Many businesses have their own aircraft that are used to fly officials and salespeople to out-of-town assignments. General aviation planes also carry cargo and passengers in areas of the world that do not have highways or railroads.

In Australia, a specialized aviation service called the Royal Flying Doctor Service supplies medical treatment to people living in remote areas. People who are ill or require medical advice use radio to contact a doctor at the nearest base. The doctor may advise the patient by radio or may arrange for a light plane to pick up the patient. Air ambulances in other parts of the world provide specially equipped airplanes to fly patients to hospitals.

Airline operations. Almost every country has at least one airline. In some countries, the government owns

Cameramann International, Ltd. from Marilyn Gartman Agency

Airline operations involve carrying cargo as well as passengers. Most commercial transport planes carry both passengers and cargo. Other transports haul cargo only.

© Lou Jones

Airport operations focus on providing runways and navigation aids as well as facilities to load, refuel, and repair planes. This photo is an aerial view of Boston's Logan Airport.

one or more airlines. Air France, for example, is mostly state-owned. During the 1990's, many governments encouraged privatization of airlines to curb costs and increase efficiency.

There are two main types of airline service—*scheduled flights* and *nonscheduled flights*. Scheduled flights are made over certain routes according to a timetable. Nonscheduled flights are mainly *charter* flights for customers who want to hire a plane to fly to a particular place at a particular time.

In the United States, airlines must receive permission from the federal government to use commercial transport planes for scheduled flights. The airlines that the government approves for such flights are called *certificated airlines*. The term *scheduled airlines* is often used in the United States for the certificated airlines, though these lines may also make some nonscheduled flights. To receive government certification, an airline's planes and pilots must meet government standards.

A majority of airlines carry both passengers and cargo. Airliners usually carry a certain amount of freight on passenger flights. In addition, a large number of passenger airlines operate transport planes that carry only cargo. A few certificated airlines in the United States specialize in carrying cargo and do not make any passenger flights.

© Heinz Steenmans, Wheeler Pictures

General aviation activities include the operation of *air taxi services*, which take small numbers of passengers on short flights. This plane flies sightseers over the Grand Canyon.

Sometimes, airlines have financial problems due to low passenger traffic, debts from purchasing new aircraft, and increasing costs, such as the rising cost of jet fuel. In the 1970's, many airlines cut their airfares and developed various bargain ticket plans to attract passengers. These steps led to huge increases in passenger traffic. High operating costs led many small airlines to merge with larger airlines. By the late 1990's, many airlines had also formed alliances for ticketing and for scheduling certain routes.

In most European countries, the government has combined two or more airlines to form a large national airline. Various European airlines have also formed consortiums to help cut expenses. The members of an airline consortium cooperate in such matters as purchasing aircraft and training pilots.

Airport operations. Airports provide the fuel and the runways, navigation aids, and other ground facilities needed for air travel. Generally, only a few of a country's airports have the facilities to handle large passenger planes. Additional small airfields serve light planes or specialized aircraft, such as helicopters or seaplanes. Cities or public corporations own most large airports. Most small airports are private airfields owned by organizations or individuals. See **Airport**.

Aviation support industries provide a wide variety of supplies and services to airlines, airports, pilots, and passengers. Some companies furnish repair services or fuel for airplanes. *Freight forwarders* make arrangements for shipping air cargo. Various food services prepare meals to be served on passenger flights. Some insurance brokers specialize in flight insurance, and some lawyers specialize in air law. Private weather bureaus supply pilots with specialized information not provided by government weather services.

Aviation agencies and organizations

Aviation agencies. A majority of countries have government agencies that enforce air safety regulations and handle related economic matters. In the United States, the Federal Aviation Administration (FAA) establishes

the rules that all planes must follow when flying in the United States. One of the agency's most important jobs is to operate a network of *air route traffic control centers* throughout the United States and its territories. Each control center uses radar and radio communications to help planes in its vicinity follow the *airways,* also called *air routes,* to which they are assigned (see **Airplane** [Air navigation]). The FAA also issues licenses to pilots. In addition, every newly manufactured airplane must be issued an FAA certificate of *airworthiness* before it may be flown. This certificate states that the airplane has been inspected and is in good flying condition. See **Federal Aviation Administration.**

Almost every U.S. state has an agency to regulate and improve aviation within its borders. These agencies handle airport construction, registration of airplanes and pilots, and similar matters. Many local governments also have aviation agencies. These agencies deal mainly with the operation and maintenance of local airports.

In Canada, the federal government regulates civil aviation. The director of civil aviation, under the supervision of the Department of Transport, deals mainly with such matters as registration of aircraft, licensing of pilots, and establishment of air navigation facilities. The Canadian Transport Commission handles the economic regulation of Canadian airlines.

Similar regulatory activities are carried out by national agencies in other countries. Such agencies include the United Kingdom's Civil Aviation Authority (CAA). These agencies are involved in such issues as air-traffic control and registration of airplanes and pilots.

The International Civil Aviation Organization is an agency of the United Nations (UN). Almost every country belongs to the ICAO. The organization sets up common air safety standards among member countries and tries to increase cooperation in other matters concerning international aviation. See **International Civil Aviation Organization.**

Other aviation organizations include various groups formed to further their own special interests. The groups include airline operators, airplane manufacturers, and pilots. For example, U.S. and Canadian airline operators belong to the Air Transport Association of America. Operators of international airlines in countries throughout the world belong to the International Air Transport Association. See **Air Transport Association of America; International Air Transport Association.**

Aircraft nationality marks

Most civil aircraft carry one or two letters or a number and a letter to identify their nationality. This *nationality mark* is painted on both sides of the fuselage or tail. It also is displayed on the underside of the wing. Numbers or letters following the nationality mark on a plane are the *registration mark* issued to that particular plane in its own country. Each country that belongs to the International Civil Aviation Organization (ICAO) reports its nationality mark to the organization. This table lists the nationality marks of selected ICAO members.

History of the aviation industry

Beginnings. The successful piloted flights of a powered airplane by Orville and Wilbur Wright in 1903 marked the beginning of the practical aviation industry. After these flights, the Wright brothers tried to sell the design for their plane to the U.S. and various European governments. But they had never made an official public flight, and government leaders were not convinced that their plane could fly.

Meanwhile, a few European inventors had also built airplanes. In the 1890's, the German glider pioneer Otto Lilienthal had manufactured a limited production series of special gliders for experimental use. In 1905, two French fliers, the brothers Charles and Gabriel Voisin, started the world's first airplane-manufacturing company. They began making a few made-to-order planes at a small factory outside Paris. Within a few years, other European fliers also started manufacturing companies. They included Louis Blériot and the brothers Henri and Maurice Farman in France; and Frederick Handley Page, A. V. Roe, and T. O. M. Sopwith in the United Kingdom.

In 1907, Glenn H. Curtiss, an American flier and airplane designer, started the first airplane company in the United States, in Hammondsport, New York. Curtiss sold his first plane to the newly organized Aeronautic Society

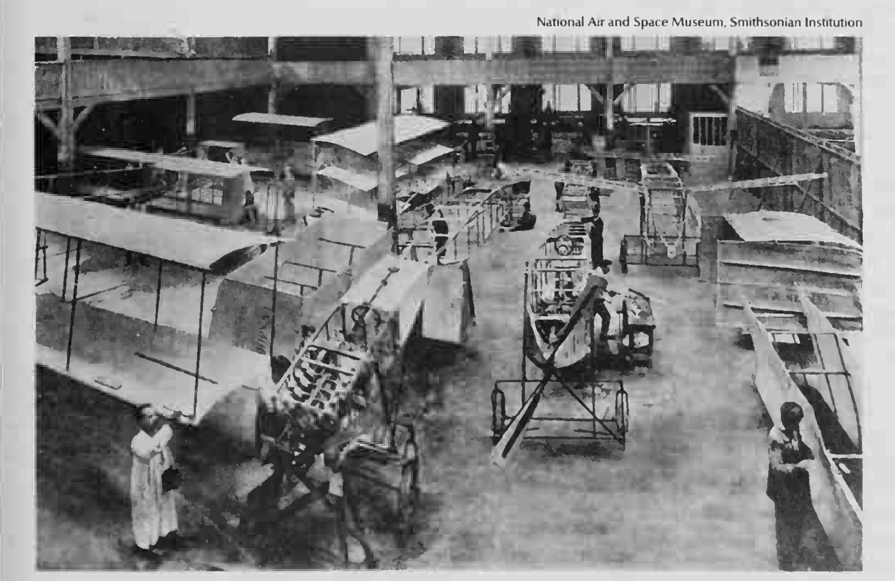
of New York for $5,000. This was the first sale of a commercial airplane in the United States.

The Wright brothers had made their first official public flight in 1908 and amazed the world with their airplane's flying ability. That same year, the U.S. Army Signal Corps ordered a specially built Wright plane, for which the government paid $30,000. This was the world's first military plane. In November 1909, a group of wealthy Americans lent the Wright brothers money to start a manufacturing firm, the Wright Company. The company had its factory in Dayton, Ohio, and its headquarters in New York City. In the autumn of 1909, a young automobile mechanic and salesman named Glenn L Martin began to manufacture airplanes in an abandoned church in Santa Ana, California. Within a few years, his company became a leading U.S. producer of military planes.

The world's first great aviation meeting was held in 1909 near Reims, France. Manufacturers displayed 38 airplanes. Several of the planes on show were offered for sale to the public—a sign of growing confidence in the airplane.

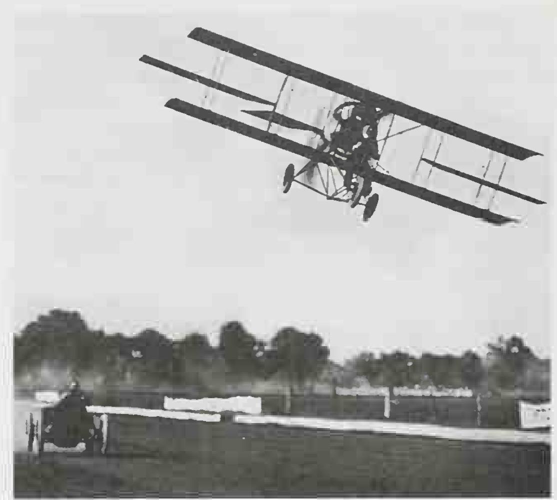
The first flying regulations. In 1905, a group of French flying enthusiasts established the Fédération Aéronautique Internationale (FAI) in Paris. One of the FAI's main duties was to regulate the sport of flying. It also ruled on world speed, altitude, and other flying records. The FAI still has this function. The Aero Club of America was also founded in 1905. It regulated flying in the United States, sponsored exhibitions and races, and issued licenses to U.S. pilots.

In 1908, Kissimmee, Florida, passed the world's first law regulating airplanes. The law required the registration of local aircraft and regulated their speed and altitude when flying over the town. In 1911, Connecticut passed the first state law regulating aviation. The law required anyone who owned or operated an airplane within the state to register the plane and obtain a pilot's license.



World War I (1914-1918). When World War I began in Europe, even the largest airplane factories turned out only a few planes a year. But the factories quickly increased their production to meet the demands of the warring nations. Airplane builders used newly designed engines to put fighters and bombers into the skies. Such well-known manufacturers as Farman, Handley Page, and Voisin built many of these planes. Other European manufacturers also became famous for their warplanes. They included Morane-Saulnier and Nieuport in France; Fokker and Junkers in Germany; and Bristol, de Havilland, Hawker, Short, and Vickers in the United Kingdom. By the end of the war, designers had created such aircraft as the British Vickers Vimy bomber and the American Curtiss NC-4, both of which flew across the Atlantic Ocean in 1919.

The United States entered the war in 1917 with about 110 military planes. The government immediately set a production goal of 29,000 airplanes a year. But the airplane companies had little or no experience with mass-production methods. The nation's automobile manufacturers, on the other hand, had developed assembly lines before the war and used them to turn out thousands of cars yearly. Various automakers helped set up assembly lines in the airplane factories.



The United States had no designs of its own for bombers or fighters. But American engineers designed a powerful airplane engine called the Liberty. Several U.S. companies began to mass-produce the United Kingdom's de Havilland D.H. 4 bombers and equip them with Liberty engines. The principal producer was the Dayton Wright Aeroplane Company, which was organized in 1917. Wilbur Wright had died of typhoid fever in 1912, and Orville sold his interest in the Wright Company to a group of investors in 1915. Although Orville had no financial interest in the Dayton Wright Company, he allowed the firm to use the Wright name in its title. The companies founded by Curtiss and Martin also became major producers of military planes during the war. Although U.S. factories did not meet their production goal of 29,000 planes a year, they had built almost 15,000 military planes by the end of the war.

In 1916, two airplane companies were established on

National Air and Space Museum, Smithsonian Institution

Early airplane factories, such as this French plant of 1908, produced only a few planes at a time—and almost entirely by hand. Mass production began with the manufacture of warplanes during World War I (1914-1918). Before the war, airplanes were used mainly for sport.

National Air and Space Museum, Smithsonian Institution

Airplanes raced against automobiles in the early days of aviation. This 1914 race at Columbus, Ohio, was between the famous auto racer Barney Oldfield and the daredevil pilot Lincoln Beachey. The finish was so close that no one knows who won.

the West Coast of the United States. They were the Boeing Company, which was founded in Seattle by William E. Boeing, and the Lockheed Corporation (now Lockheed Martin Corporation), which was founded in Santa Barbara, California, by the brothers Allan and Malcolm Loughead. The Boeing and Lockheed companies were too small to make many planes during the war. But in time, they became two of the nation's leading aircraft manufacturers.

The first airlines. The Wright brothers and other early fliers occasionally took passengers for short plane rides. In 1910, a Wright airplane flew 70 pounds (32 kilograms) of silk from Dayton to Columbus, Ohio—perhaps the first air freight shipment in history. The world's first regular airplane passenger service began in the United States in 1914, but it lasted only a few months. A pilot named Tony Jannus used a small seaplane to fly passengers across Tampa Bay, between St. Petersburg and Tampa, Florida. On May 15, 1918, the U.S. government started the world's first permanent airmail service. Army pilots flew the mail between New York City, Philadelphia, and Washington, D.C.

After World War I, thousands of military planes became available for civilian use. In 1919, bombers were used to start nearly 20 small passenger airlines in France, Germany, the United Kingdom and several other European countries. One of these airlines, founded by Henri and Maurice Farman, began the world's first regular international airline service. The company used old Farman bombers to make weekly passenger flights between Paris and Brussels, Belgium.

By 1924, passenger airlines were operating in 17 European countries as well as in Africa, Australia, and South America. Several of these airlines are still active. They include Royal Dutch Airlines (KLM) of the Netherlands, Germany's Lufthansa, and Australia's Queensland and Northern Territory Aerial Services (QANTAS). Beginning in the mid-1920's, the governments of many countries started to combine two or more private airlines to form a large national airline. In 1924, the United Kingdom became the first major power to form a national, government-owned airline, Imperial Airways.

Aviation progress. Many small passenger airlines were formed during the early 1920's. But most lasted only a few months because they could not attract enough customers. Most people considered flying a dangerous sport rather than a safe means of transportation.

In the United States, the federal government's main interest in aviation was to improve airmail service. In 1920, airmail routes extended from New York City to San Francisco. Mail planes operated only during the day, however. To help the mail pilots fly their open-cockpit planes at night, the government installed beacon lights at airports along the transcontinental route. Each light could be seen as far as 50 miles (80 kilometers) away. By 1924, night-flying techniques enabled planes to get mail from New York City to San Francisco in 24 hours.

In 1925, the U.S. Congress passed the Kelly Air Mail Act, which gave private airlines the job of flying the mail. The government then signed contracts with 11 companies formed to carry the mail. Henry Ford, the famous automobile maker, owned one of these airlines. In 1926, Ford's airline became the first airline to carry U.S. mail. Within a few months, all 11 companies were flying mail between major U.S. cities. Some of the airlines also began carrying passengers. In 1926, airlines in the United States carried only about 6,000 passengers. In 1930, they carried more than 400,000.

Several U.S. aircraft companies were also started during the 1920's. In 1920, an engineer named Donald Douglas helped organize an aircraft company in Santa Monica, California. It became the Douglas Company the following year, later part of McDonnell Douglas Corporation, and later still part of the Boeing Company. In 1923, the Consolidated Aircraft Corporation was founded in East Greenwich, Rhode Island. It took over the air-

National Air and Space Museum, Smithsonian Institution

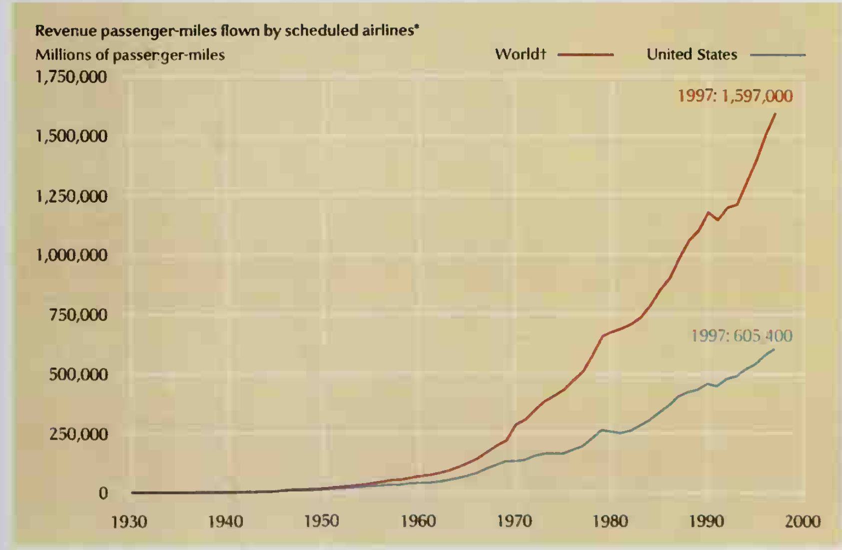
Post-office planes began flying U.S. mail in 1918. This plane is being loaded with mail for a transcontinental flight in 1923. Private airlines began flying the mail in 1926.

United Airlines

Early airliners like this Ford Tri-Motor carried about 10 passengers, who bundled up in coats to keep warm. This Tri-motor was flown by National Air Transport (NAT), one of the first successful U.S. airlines. NAT began carrying mail in 1926 and passengers in 1927. It became part of United Airlines in 1931.

plane designs of the Dayton Wright Company. The Pratt and Whitney Company began making aircraft engines in Hartford, Connecticut, in 1925. In 1929, the Curtiss and Wright companies merged to form the Curtiss-Wright Corporation. Grumman Aircraft (now part of Northrop Grumman Corporation) also started business in 1929 on Long Island, New York.

The rapid increase in aviation activity led Congress to pass the Air Commerce Act in 1926. This act was the first federal law to regulate aviation in the United States. It provided for a system of airways and navigation aids across the country. The act also called for rules governing the manufacture of airplanes and the licensing of airplanes and pilots. A Bureau of Air Commerce was set up to carry out these measures.



The industry comes of age. Air transport continued to grow during the early 1930's. By 1935, the United States had four major domestic airlines—American, Eastern, Transcontinental and Western Air (later called Trans World Airlines), and United. Smaller regional airlines included Braniff, Delta, and Northwest. The country also had a major international airline—Pan American World Airways (Pan Am)—which flew to Latin America. Many European governments continued to form large national airlines, such as Air France and Italy's Ala Littoria (now Alitalia).

To meet the growing demand for faster, larger airliners, manufacturers began to produce twin-engine planes, such as the Boeing 247 and the Douglas DC-3. The DC-3 appeared in 1935 and soon became the world's most popular transport plane. A number of companies, including Martin (now Lockheed Martin Corporation) in the United States and Short in the United Kingdom, started to make large, four-engine seaplanes called *flying boats.* In the 1930's, flying boats made the first passenger flights across oceans. New firms were also started in the 1930's, such as North American Aviation and United Aircraft (now United Technologies), which took over production of Pratt and Whitney engines.

By the late 1930's, flying was an important means of travel in most of the world. In 1938, the world's airlines carried nearly 3 ½ million passengers.

The rapid growth of civil aviation created a need for more effective government regulation. In 1938, the U.S. Congress established the Civil Aeronautics Authority to

Growth of airline passenger traffic

This graph shows the growth of passenger traffic for United States airlines and for the world since 1930. Passenger traffic, especially the world total, has risen sharply since 1965.

*A passenger-mile is one passenger carried 1 mile (1.6 kilometers).
†World total includes statistics for member countries of the International Civil Aviation Organization (ICAO).
Sources: ICAO; U.S. Department of Transportation.

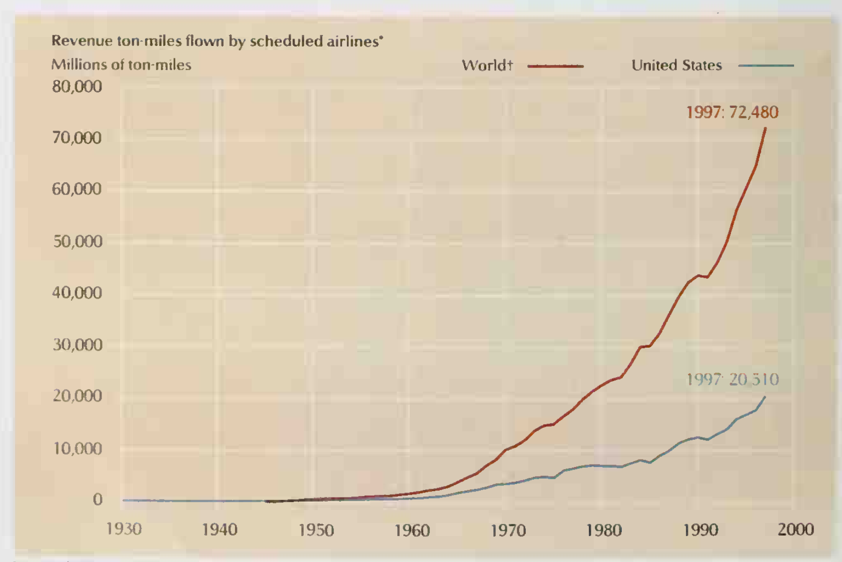
deal with every aspect of civil aviation. The authority included a five-member board, which, in 1940, became the Civil Aeronautics Board. It also included an administrative office, which became the Civil Aeronautics Administration (CAA) in 1940.

World War II (1939-1945). The peace treaty that ended World War I prohibited the manufacture of military aircraft in Germany. Nevertheless, several German aircraft firms were founded during the 1920's. They included the famous Heinkel and Messerschmitt companies. In the mid-1930's, Heinkel, Messerschmitt, and other German firms, such as Dornier and Junkers, secretly made hundreds of bombers and fighters for the German air force. On Sept. 1, 1939, German dive bombers attacked Poland, and World War II began. One European country after another fell to the Germans. Finally, the United Kingdom was left nearly alone to fight off the German air force. British aircraft companies, such as Avro, de Havilland, Handley Page, Hawker, and Supermarine, quickly increased their production of warplanes.

The United States produced about 2,100 military planes in 1939. Both Germany and Japan had larger air forces. The huge Mitsubishi corporation produced many of Japan's warplanes, including the famous Zero fighter. After the United States entered the war in December 1941, U.S. airplane production increased greatly. More than 40 companies took part in a gigantic effort to supply the United States and its allies with military planes. Many companies enlarged their factories and hired additional workers. Assembly lines began working round the clock. By 1944, production had reached nearly 100,000 transport planes, bombers, and fighters a year.

By the end of the war, U.S. factories had built more than 300,000 aircraft. Germany, Japan, the Soviet Union, and the United Kingdom had also produced many thousands of planes. During the war, aircraft production had become the world's leading manufacturing industry.

Boeing Co.



Huge flying boats began carrying passengers on ocean flights during the 1930's. In 1939, Pan American World Airways used this Boeing 314 Clipper to start regular transatlantic service.

A new age of flight. In 1937, British inventor Frank Whittle built the first successful jet engine. The first jet airplanes were developed for military use. Germany flew the first jet aircraft in 1939. By 1942, both the United Kingdom and the United States had developed experimental jet planes for military use.

After World War II, aircraft manufacturers began the development of jet airliners. In 1952, British Overseas Airways Corporation (BOAC), now British Airways, started jet passenger flights with de Havilland Comets. But the flights were stopped after several Comets exploded in the air. Investigators discovered serious flaws in the plane's structure. De Havilland engineers then designed an improved Comet. In 1958, BOAC used the new Comets to begin jet passenger service across the Atlantic

Growth of airline cargo traffic

This graph shows the growth of cargo traffic for United States airlines since 1930. It shows the growth of world cargo traffic since 1945, when accurate world totals became available. Cargo traffic has increased sharply since 1960.

*A ton-mile is 1 ton (0.9 metric ton) carried 1 mile (1.6 kilometers).
†World total includes statistics for member countries of the International Civil Aviation Organization (ICAO).
Sources: ICAO, U.S. Department of Transportation.

Ocean. American companies also built successful jet transports in the late 1950's, and these aircraft quickly dominated international air transportation. In 1959, American Airlines used the first of these—the Boeing 707—to start transcontinental jet service from New York City to Los Angeles.

The beginning of jet airline service created new challenges. Large jetliners carried nearly 200 passengers, and the crash of one of these planes could cause heavy loss of life. New hazards were also created along the world's air routes as airplanes flew faster and in greater numbers than ever before. In 1958, the U.S. government combined the CAA and several other agencies to form the Federal Aviation Agency. The agency was given the job of establishing and enforcing air safety regulations and air traffic procedures in the United States. It was renamed the Federal Aviation Administration in 1967.

By 1970, jet transports had replaced propeller-driven planes on most major airlines. In 1970, Pan Am became the first airline to offer jumbo jet service, using Boeing 747's. France and the United Kingdom began passenger service with their SST, the Concorde, in 1976.

Industry mergers. Beginning in the 1950's, several large aerospace companies were formed by mergers. In 1954, the General Dynamics Corporation took control of Consolidated Vultee (Convair). In 1967, McDonnell Aircraft merged with Douglas Aircraft to form the McDonnell Douglas Corporation, and North American Aviation and Rockwell-Standard merged, forming the North American Rockwell Corporation. In 1973, this firm merged with Rockwell Manufacturing Company to become Rockwell International Corporation.

Internationalization became an important trend in the aviation industry beginning in the 1960's. The term refers to cooperative manufacturing programs in which firms from different nations share research, development, and production costs. The consortium formed by the British and French to build the Concorde SST was an early program of this type. Another successful program has been Airbus. This consortium, which manufactures commercial transport aircraft, has involved most countries in Western Europe.

United States aviation firms moved slowly into internationalization in the 1970's. Manufacturers in Canada, Italy, Japan, and the United Kingdom produced major parts of the McDonnell Douglas DC-10 transport, which began commercial service in 1971. Some U.S. firms have formed partnerships with foreign companies to manufacture European-designed aircraft in the United States. For example, during the 1980's, McDonnell Douglas produced the British-designed Harrier—a V/STOL (Vertical/Short Take-Off and Landing plane)—in partnership with British Aerospace (see **V/STOL**).

Airline safety concerns. Beginning in the 1960's, airliner hijacking, also called air piracy, became a serious problem. In 1970, hijackers throughout the world seized 49 airliners and forced the pilots to fly to destinations off their routes, often to other countries. In the 1980's, terrorist sabotage became a serious risk as several airliners were blown up in flight.

In response to the hijackings, aviation authorities tightened airport security regulations. These regulations include the inspection of aircraft, passengers, and baggage for hidden guns, bombs, or other weapons. Most countries have laws against hijacking and terrorism. But laws differ from country to country. The ICAO develops procedures to help member countries establish consistent methods to prevent and investigate hijackings. See **Airport** (Airport security); **Hijacking**; **Terrorism**.

Deregulation of the U.S. airlines. In the late 1970's, the Civil Aeronautics Board began to ease its controls over airline fares and routes in the United States to encourage greater competition and better service. In 1978, Congress passed the Airline Deregulation Act. This law provided for the gradual removal of economic controls of the airline industry. The Civil Aeronautics Board was dissolved in 1984. New airlines soon began to form, and existing ones rapidly expanded their services.

Recent developments. Deregulation in the United States allowed domestic airlines to compete in many international markets. U.S. airlines formed alliances with overseas carriers to simplify ticketing. Many developed *hub and spoke* systems, in which many flights connect at a central airport. In manufacturing, several mergers in the 1990's led to the disappearance of historic U.S. airplane builders, such as McDonnell Douglas, which merged into Boeing. International partnerships became increasingly significant, with Airbus capturing one-third of the world market in jet airliner sales in the 1990's.

On Sept. 11, 2001, terrorists hijacked four commercial airplanes, deliberately crashing two into the towers of the World Trade Center in New York City and one into

Important dates in aviation history

1903	Orville and Wilbur Wright of the United States made the world's first successful airplane flights.
1905	Charles and Gabriel Voisin of France started the first airplane-manufacturing company.
1907	Glenn H. Curtiss started the first airplane-manufacturing company in the United States.
1914	The world's first scheduled airline began service across Tampa Bay between St. Petersburg and Tampa, Florida. But the airline lasted only a few months.
1918	The U.S. government used Army pilots to start the world's first permanent airmail service.
1919	The first successful scheduled airlines began to operate in Europe. They used converted World War I bombers.
1925	Private airlines began carrying U.S. airmail.
1926	The first successful scheduled airlines in the United States began operations.
1926	The U.S. Congress passed the Air Commerce Act, the first federal law to regulate aviation in the United States.
1952	British Overseas Airways Corporation (now British Airways) started jet passenger service with de Havilland Comets.
1958	The U.S. Congress established the Federal Aviation Agency (FAA) to deal with air safety and air traffic control. The agency became the Federal Aviation Administration in 1967.
1959	American Airlines started jet service across the United States with Boeing 707's.
1970	Pan American World Airways (Pan Am) began jumbo jet service with Boeing 747's.
1970	A group of Western European countries founded Airbus to compete with U.S. production of jet airliners.
1976	Air France and British Airways began passenger service with supersonic transport planes.
1984	The Civil Aeronautics Board was dissolved as part of the U.S. government plan to deregulate the airline industry.
2001	In response to terrorist attacks in New York City and Washington D.C. on September 11, the U.S. Congress created the Transportation Security Administration to take over air safety functions from the FAA.

the Pentagon Building outside Washington, D.C. The fourth hijacked plane crashed in Somerset County, Pennsylvania. After the hijackings, U.S. airports and airlines sought new ways to protect against terrorist attacks. Congress passed legislation requiring federal employees to handle all passenger and baggage inspection in U.S. airports by the end of 2002. A newly created agency, the Transportation Security Administration, took over air safety functions from the FAA.

Careers in aviation

The aviation industry employs many kinds of skilled workers. They include aeronautical engineers, computer specialists, electricians, flight attendants, flight engineers, flying instructors, mechanics, pilots, radar specialists, and radio operators. In the United States, many jobs in the aviation industry require FAA certification. For example, air traffic controllers, aviation mechanics, flight engineers, and pilots must have FAA certificates.

Some schools offer courses in preparation for such careers as aviation mechanic, computer specialist, and radio operator. Aeronautical engineering and some other highly skilled professions require a college education. Most pilots obtain their training at flying schools or in military service. Some high schools and colleges also offer courses in flying. See **Airplane** (Learning to fly).

Jobs in general aviation. Many pilots work for air taxi services, business firms, and other organizations that use light planes. In many countries, flying light planes for commercial purposes requires a *commercial pilot license.* In the United States, the FAA issues these licenses to pilots 18 years old or over who have at least 200 hours of flying experience and who pass the physical, written, and flight examinations.

Jobs with airlines and airports. In most countries, airline pilots and copilots must obtain a special license. They must pass a thorough physical examination, as well as written and flight examinations. In the United States, airline pilots and copilots must have an FAA *airline transport pilot license.* To obtain this license, they must be at least 23 years old and have a commercial pilot license and 1,500 hours of flight time.

Some airlines use flight engineers. On long flights, the engineers watch the many instruments in the cockpit that tell how the engines are operating. Most airlines require their flight engineers to have a commercial pilot license. Airlines prefer to hire flight attendants who have some college, business, or nursing training. Skilled mechanics are needed for airliner maintenance.

Jobs in the aircraft industry. Aircraft manufacturers hire electricians, machine tool operators, mechanics, and other skilled workers to make and assemble the many parts of airplanes. The industry also employs various types of engineers to design aircraft and experienced pilots to test-fly planes.

Jobs with government agencies. Government agencies in many countries hire radar and radio operators to work at air route traffic control centers and airport control towers. They also hire mechanics and pilots to serve as safety agents. Many local aviation agencies also require engineers, mechanics, pilots, and other skilled people. Some large cities hire pilots to serve as flying police officers or to perform rescue services.

Aviation medicine. See Aerospace medicine.

Avicenna, *AV ih SEHN uh* (980-1037), also known as Ibn-Sina, *IHB uhn SEE nah,* was a Muslim physician, philosopher, astronomer, and poet. He wrote *Canon of Medicine,* which was used as a medical text for over 600 years. It is still occasionally used in Asia. Avicenna's major philosophical work, *The Cure,* presented his interpretation of the philosophy of Aristotle. Of all his books, it had the greatest effect on Western thought. Avicenna was born near Bokhara (now Bukhara in Uzbekistan) in what was then a part of Persia ruled by the Samanid dynasty. He began to practice medicine at 16. When only 20, he was known as the most learned person of his time. See also Geology (The Romans). Matthew Ramsey

Avignon, *ah vee NYAWN* (pop. 88,312; met. area pop. 253,580), is an agricultural center and a historic city in southeastern France. It lies along the Rhône River in one of the richest agricultural regions in France. For location, see France (political map).

Giorgio Ricatto, Shostal

The Papal Palace in Avignon was the home of the popes of the Roman Catholic Church from 1309 to 1377. The building at the far left, topped by a statue of the Virgin Mary, is the cathedral. The other buildings are part of the palace complex.

Avignon is a trading center for wine, fruits, vegetables, and other products produced in its area. Other economic activities include shipping, food processing, and the manufacture of chemicals, leather, machine tools, soap, and textiles. A major theater festival is held there each summer. The city is the capital of the Vaucluse *department* (administrative district).

Roman soldiers established a colony on the site of what is now Avignon in the 100's B.C. From 1309 to 1377, Avignon served as the home of the popes and, as such, the center of Christianity (see Pope [The troubles of the papacy]). The Papal Palace, where the popes lived, is an architectural masterpiece and a major tourist attraction. Walls that were built around the city to protect the popes still stand. Mark Kesselman

Ávila Camacho, *AH vee LAH kah MAH choh,* **Manuel,** *mah NWEHL* (1897-1955), a Mexican soldier, diplomat, and political leader, served as president of Mexico from 1940 to 1946. As president, he promoted closer relations with the United States and encouraged U.S. investment in Mexico. During World War II (1939-1945), he allied Mexico with the United States against the Axis Powers and initiated the *bracero* (day laborer) program. This program sent Mexican agricultural workers to the United States. See Mexico (The mid-1900's).

Ávila Camacho was born on THAWN, in Teziutlán, Puebla, Mexico. When he was 17, he joined the uprising led by Venustiano Carranza against President Victoriano Huerta (see Carranza, Venustiano). He later fought with Lázaro Cárdenas and Plutarco Elías Calles against the rebellion of Adolfo de la Huerta in 1923. Ávila Camacho served as secretary of national defense under Cárdenas. W. Dirk Raat

Avocado is a fruit that grows in tropical and subtropical climates. The fruit may be round, oval, or pear-shaped. Its skin color ranges from green to dark purple, depending on the variety. Avocados have a yellow-green pulp and contain one large seed.

Avocados are highly nutritious. They are rich in vitamins, minerals, and oil. People eat avocados fresh in dips, salads, and desserts. Guacamole, a popular Mexican dish, is made with mashed avocados, onions, tomatoes, cilantro, garlic, and salt. In Brazil, avocados are used to make milk shakes and ice cream.

Avocados are native to Mexico, Guatemala, Jamaica, and Cuba, but they are now grown in many parts of the world. The United States is the leading avocado-producing country, followed by Mexico and Brazil. California and Florida produce most of the U.S. avocado crop.

Avocado trees grow up to 30 to 60 feet (9 to 18 meters) tall. They have spreading branches with dark green leaves and small, greenish-white flowers. In some varieties, it is estimated that only one fruit is harvested for every 5,000 flowers. To help guarantee fruit development and uniformity, the stems of avocado seedlings

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd

Avocados have a yellow-green pulp that surrounds one large seed. Avocado trees bear broad leaves and small flowers.

are grafted to the stems of selected varieties.

The many varieties of avocados are divided into three main groups—(1) Mexican, (2) Guatemalan, and (3) West Indian. Mexican avocados have smooth, thin skins. The fruits are small and seldom weigh more than $\frac{1}{2}$ pound (0.2 kilogram). Guatemalan avocados have thick, rough skins, and they may weigh more than 3 pounds (1.4 kilograms). West Indian avocados are about the same size as the Guatemalan fruits, but they have leathery skins.

Jaime E. Lazarte

Scientific classification. The avocado is a member of the laurel family, Lauraceae. Its scientific name is *Persea americana.*

WORLD BOOK illustration by John Rignall, Linden Artists Ltd.

The American avocet is a wading bird whose long legs and long, curved bill help it feed in shallow-water areas.

Avocet, *AV uh seht,* is a type of long-legged wading bird. The *American avocet* is most common west of the Mississippi River, from Canada to the Mexican border. It is about 17 inches (43 centimeters) long and has a white body and black wings. The head and neck are streaked with brown during the breeding season. The long, flat bill curves upward. Another avocet species, the *pied avocet,* lives throughout much of Africa, Asia, and Europe. Pied avocets resemble American avocets, except they have both black and white plumage on the head.

The avocet feeds by scraping its bill along the bottom of shallow pools of water. In this way it collects small water animals, which it eats. It also eats other food that floats on or in the water. Harmful insects form part of its diet. Fritz L. Knopf

Scientific classification. Avocets belong to the stilt and avocet family, Recurvirostridae. The scientific name for the American avocet is *Recurvirostra americana.* The pied avocet is *R. avosetta.*

Avogadro, *AH vuh GAH droh,* **Amedeo,** *AH mah DEE oh* (1776-1856), was an Italian physicist. He proposed in 1811 his famous hypothesis, now known as *Avogadro's law.* The law stated that equal volumes of all gases at the same temperature and pressure contain the same number of chemical units. Avogadro distinguished between gases composed of complex units (molecules) and gases made up of simple units (atoms). He was able to calculate atomic and molecular weights from gas densities (see Atom [Atomic weight]). Avogadro's hypothesis was not accepted by the leading scientists of his time. His hypothesis was discounted until 1858, when Italian chemist Stanislao Cannizzaro reintroduced it and developed it further. Avogadro was born on Aug. 9, 1776, in Turin. See also **Chemistry** (Development of physical chemistry). Melvyn C. Usselman

Avoirdupois, *AV uhr duh POYZ,* is a system of weights used for common commodities such as coal, grain, and foodstuffs. The system is used primarily in the United States. The word *avoirdupois* comes from French words meaning *goods of weight.* The basis of the system is the pound, which equals 0.454 kilogram. An avoirdupois pound contains 16 ounces or 7,000 grains. Each ounce contains 16 drams, so 1 dram equals 27.344 grains. One grain equals 64.799 milligrams. Two other systems of weight, the *Troy* and *apothecaries'* systems, also have grains that equal 64.799 milligrams. The Troy and apothecaries' pounds, however, equal 5,760 grains.

Ax, also spelled *axe,* is a cutting tool made up of an edged head attached to a handle. Some axes have double-edged heads. The head is steel or a steel alloy. The handle is hardwood or plastic and fits into a hole in the ax head called the *eye.* Axes have different shapes and sizes, depending on their uses. They include the *firefighter's ax,* used to fight fires; the *logging ax,* used to cut trees into logs; and the *hatchet,* a small ax used to drive roofing nails or trim tree branches. The *battle-ax* was a weapon of the Middle Ages. Alva H. Jared

See also **Tomahawk.**

Axiom, *AK see uhm,* is a mathematical statement that is assumed to be true. Axioms are considered to be self-evident truths that cannot be proved. An example of an axiom is the *parallel axiom* of geometry. The parallel axiom states that "through a point not on a given line, one, and only one, line may be drawn that is parallel to the given line."

The ancient Greeks distinguished between axioms and *postulates.* Postulates were considered to be assumptions that applied only to geometry, but axioms applied to any field of mathematics. Today, most mathematicians no longer make this distinction.

Mary Kay Corbitt

See also **Geometry** (Axiomatic organization).

Axis refers to alliances formed among Germany, Italy, and Japan before and during World War II (1939-1945). In 1936, Italy and Germany joined together in an alliance called the Rome-Berlin Axis. The term *Axis* was used to suggest that all Europe rotated about a line between these two capitals. Japan joined the alliance in 1940, and

it became the Rome-Berlin-Tokyo Axis. Bulgaria, Hungary, Romania, and the German-created states of Croatia and Slovakia became Axis satellites. The inability of the major Axis powers to forge an effective alliance helped the Allies win World War II. See also **World War II** (table; maps). Donald M. McKale

Ayckbourn, *AYK bawrn,* **Alan** (1939-), is a British playwright known for dark comedies about middle-class life. The audience laughs at his characters but often realizes that they lead sad, empty lives. For example, in *Woman in Mind* (1985), a neglected homemaker invents an imaginary family who become more real to her than her own family. Ayckbourn is noted for the clever use of stage space and dramatic structure. *The Norman Conquests* (1973) is really three plays, each about events set in different parts of a country home at the same time. In *Taking Steps* (1979), one set represents three places. The plays *House* and *Garden* (both 2000) are performed in two separate theaters by the same cast at the same time.

Ayckbourn first gained international notice with *How the Other Half Loves* (1969). His other plays include *Absurd Person Singular* (1972), *Absent Friends* (1974), *Bedroom Farce* (1975), *Sisterly Feelings* (1979), *A Small Family Business* (1987), *Man of the Moment* (1988), *The Revengers' Comedies* (1989), *Communicating Doors* (1994), *Things We Do for Love* (1997), and *Comic Potential* (1999).

Ayckbourn is the artistic director of the Stephen Joseph Theatre-in-the-Round in Scarborough, where most of his comedies premiere. He was born on April 12, 1939, in London. He was knighted in 1997.

Gerald M. Berkowitz

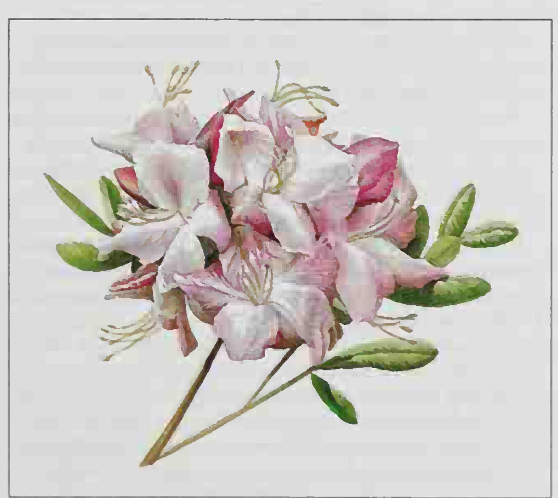
Aycock, Charles Brantley (1859-1912), was a leader in developing public school education in the South. As governor of North Carolina from 1901 to 1905, he brought about increased school appropriations, the first rural high schools, and many new teacher-training facilities. Educational reformers used his legislation as a model in much of the South.

Aycock was born on Nov. 1, 1859, in Wayne County, North Carolina. He graduated from the University of North Carolina with a law degree in 1880. A statue of Aycock represents North Carolina in the U.S. Capitol.

Eric F. Goldman

Anthony and Elizabeth Bomford, ARDEA

The aye-aye lives in the forests of Madagascar. Its large eyes and ears help it move around easily at night.



Aye-aye, *EYE eye,* is a rare animal of Madagascar that belongs to the group called *lemurs.* It has brownish fur and a long, bushy tail. The animal measures about 3 feet (1 meter) long, including the tail. It has large eyes and ears. It is most active at night, when it hunts insects for food. The aye-aye uses its long, narrow third finger to draw boring insects out of their tunnels in tree trunks. During the day, the aye-aye hides in its nest of twigs built in a tree in the forest. The aye-aye is an endangered species. The growth of villages destroys the forest that the animals need to survive. Madagascar's government forbids aye-aye hunting. It has set up reserves to protect the species. See also **Lemur.** Clyde Jones

Scientific classification. The aye-aye is in the family Daubentoniidae and the order Primates. Its scientific name is *Daubentonia madagascariensis.*

Ayllón, *eyel YAWN,* **Lucas Vásquez de** (1480?-1526), a Spanish colonizer, founded the first European settlement in what is now the United States. The settlement, on what is now the nation's southeast coast, survived for only about six months.

Ayllón was born in Toledo, Spain. In 1504, he arrived in the Americas and served as a judge for the Spanish government on the island of Hispaniola. Ayllón became wealthy, partly by trading in Indian slaves. He also sponsored voyages to the coast of what may have been present-day South Carolina or Georgia. The first voyage, made in 1521, was led by Spanish explorer Francisco Gordillo. Ayllón heard reports that the land Gordillo saw, called Chicora by the Indians, was rich in natural resources and resembled southern Spain. In 1526, Ayllón led an expedition of about 600 people to colonize Chicora. The colony Ayllón founded, called San Miguel de Gualdape, was probably on Sapelo Sound in what is now Georgia. The colonists soon suffered from starvation and disease. Many, including Ayllón, died there. The survivors returned to Hispaniola. Helen Delpar

Azalea, *uh ZAYL yuh,* is the name of a group of flowering shrubs. Azaleas grow mostly in North America and eastern Asia. Most North American azaleas are *deciduous*—that is, they lose their leaves every autumn. Asian

WORLD BOOK illustration by Robert Hynes

Azalea flowers have five tapering petals that may be pink, red, white, yellow, or purple. The flowers bloom in May and June.

species usually are evergreen and remain green all year. Azaleas can be grown in gardens. These plants also occur wild in woodlands, often in swamp areas.

Azalea blossoms range in color through all shades of pink, red, white, yellow, and purple. Their long, conspicuous *stamens* (stalks that contain pollen) extend beyond the petals. A long, slender capsule covered with hairlike parts holds the seeds.

Over 50 species of azaleas grow in North America. These shallow-rooted plants live best in well-drained acid soil. They especially thrive in partial shade with filtered sunlight. Azalea plants bloom during the months of May and June. Fred T. Davies, Jr.

Scientific classification. Azaleas belong to the heath family, Ericaceae. They make up part of the genus *Rhododendron.*

See also Bonsai (picture); Heath.

Azerbaijan, *AH zuhr by JAHN,* is a country in the Caucasus Mountain region on the western shore of the Caspian Sea. It is located mostly in southwestern Asia, but part of northern Azerbaijan is located in Europe. An area of Azerbaijan called the Naxcivan Autonomous Republic lies west of the rest of the country, separated from it by Armenian territory.

The country's full name in Azerbaijani, the official language, is Azarbayjan Respublikasy (Azerbaijan Republic). Baku is its capital and largest city. Azerbaijan became independent in 1991, after nearly 70 years as a part of the Soviet Union.

Government. Under Azerbaijan's Constitution, which became effective in 1995, the president is the country's most powerful government official. The people elect the president to a five-year term. A Cabinet of Ministers, headed by a prime minister, helps carry out the operations of government. The president appoints the Cabinet members. A 125-member parliament called the Milli Majlis (National Assembly) makes the country's laws. Voters elect the assembly members to five-year terms.

The main units of local government include the Naxcivan Autonomous Republic and districts, cities, and villages. Each unit elects a governing council to manage local affairs. All citizens 18 years old or older may vote.

Azerbaijan's highest court is the Supreme Court. There are also regional courts.

About 85,000 people serve in Azerbaijan's armed forces. Beginning at the age of 18, men must serve 17 months in the armed forces.

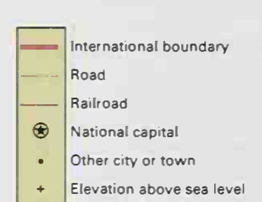
People. Most of the people are Azerbaijanis. Armenians and Russians make up the largest minority groups.

In Azerbaijan's cities, most people live in multistory apartment buildings. In rural areas, most of the people live in one- or two-story houses.

Most Azerbaijanis are Shiite Muslims. Most Armenians are Christians, and many belong to the Armenian Church, an Eastern Orthodox Church. Many Russians are Russian Orthodox Christians.

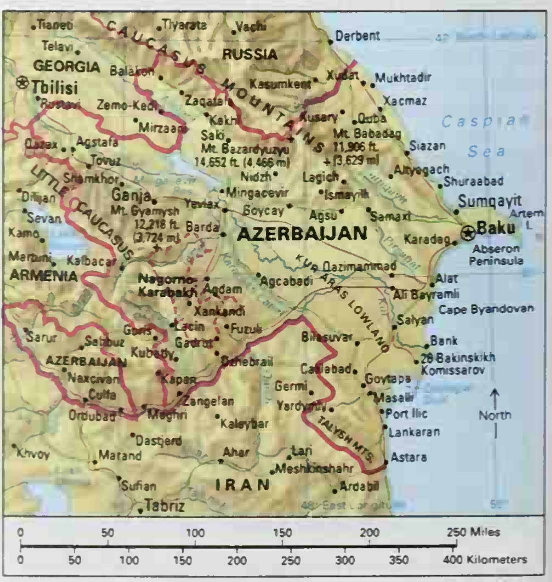
Most people in Azerbaijan wear Western-style clothing. On holidays, some men wear a traditional costume consisting of pants, a long shirt, boots, and a long jacket. Some rural women wear wide skirts and blouses with long, wide sleeves. Muslim women in rural areas often wear a black shawl that covers the head and shoulders and may be drawn over the face. The wearing of the shawl is based on a Muslim custom.

The Azerbaijani language developed from the languages of Persians and Turkic people who once inhabited the region. Today, Azerbaijani closely resembles the modern Turkish language.



Azerbaijanis enjoy *pilaf* (a rice dish) and a variety of grilled and boiled meats, including beef, goat, and lamb. Traditional dishes include *bozartma* (mutton stew) and *dovga* (soup made of yogurt, meat, and herbs). Tea and wine are popular drinks.

Soccer is a popular sport in Azerbaijan. Many people walk or swim for recreation. Men spend much of their



Facts in brief

Capital: Baku.
Official language: Azerbaijani.
Area: 33,436 mi² (86,600 km²). *Greatest distances*—north-south, 240 mi (385 km); east-west, 295 mi (475 km).
Elevation: *Highest*—Bazardyuzyu, 14,652 ft (4,466 m) above sea level. *Lowest*—Caspian Sea coast, 92 ft (28 m) below sea level.
Population: *Estimated 2002 population*—7,854,000; density, 235 per mi² (91 per km²); distribution, 52 percent urban, 48 percent rural. *1989 census*—7,021,178.
Chief products: *Agriculture*—cotton, fruit, grain, livestock, tea, tobacco, vegetables. *Manufacturing*—machine building, petroleum refining, processing of chemicals, textile production. *Mining*—aluminum, copper, iron, natural gas, petroleum, salt.
Flag: The flag's three horizontal stripes are light blue, red, and green. In the flag's center is a white crescent and star.
Money: *Basic unit*—manat. One hundred qepik equal one manat.

Baku, Azerbaijan's capital, lies on the Caspian Sea. It serves as the country's chief port. Refineries in Baku process petroleum, Azerbaijan's chief source of income.

leisure time talking with one another in teahouses.

Azerbaijanis are known for their handwoven rugs. Also, their brightly patterned shawls are highly admired.

Nearly all adults in Azerbaijan can read and write. The government requires children to attend school from the ages of 6 to 17. The country has 17 schools of higher education.

Land and climate. The Caucasus Mountains rise in northern Azerbaijan, and the Little Caucasus Mountains stretch across the western part of the country. The area north of the Caucasus Mountains is considered part of Europe. The area south of the range is considered part of Asia. Azerbaijan's highest mountain, Bazardyuzyu, rises 14,652 feet (4,466 meters) above sea level in the Caucasus Mountains.

The rugged Armenian Plateau, a land broken by deep gorges, covers part of southwestern Azerbaijan. The Kur, the country's main river, flows through the central valley between the mountain ranges and across a broad, dry plain called the Kur-Aras Lowland. From the lowland, the Kur drains into the salty Caspian Sea. The Kur's main tributary, the Aras, flows along part of Azerbaijan's southern border. Other important rivers in Azerbaijan include the Terter and the Akera. The rivers serve as a source of irrigation water and energy. The Mingacevir dam on the Kur River provides hydroelectric power for Baku and the Ganja industrial region.

Summers in the lowlands are long and hot. Winters are cool. The lowlands have an average temperature of 79 °F (26 °C) in August and 39 °F (4 °C) in January. Parts of the Caucasus Mountains have average temperatures of 56 °F (13 °C) in August and 21 °F (6 °C) in January. Annual precipitation ranges from about 5 to 15 inches (13 to 38 centimeters) in most of the country's lowland areas. The highlands and a region in southeastern Azerbaijan on the Caspian Sea receive about 40 to 55 inches (100 to 140 centimeters) of precipitation every year.

Economy. The government controls most of Azerbaijan's economy. Industry accounts for about half of the value of economic production. The country's industrial activities include machine building, mining, petroleum refining, the processing of chemicals, and textile production. The chief industrial centers are Baku, Ganja, Saki, Xankandi, and Naxcivan.

Petroleum ranks as the country's most important mineral product by far. It is Azerbaijan's chief single source of income. The largest producing oil fields lie in the Baku region, in the Caspian Sea, and on the sea's western shore. Azerbaijan's other mineral products include aluminum, copper, iron, natural gas, and salt.

Agriculture accounts for about a third of the value of economic production. About 70 percent of the farmland is irrigated. Farmers in the lowlands grow such crops as cotton, fruit, grain, tea, tobacco, and vegetables. Some farmers raise silkworms for the raw silk industry. Herders raise cattle, goats, and sheep on mountain slopes. The Caspian Sea is a source of fish.

Azerbaijan has a limited road and railway system. A port at Baku handles most of the country's trade on the Caspian Sea. The main airport is located at Baku.

Azerbaijan's main radio and television stations broadcast from Baku. The country publishes newspapers and magazines in Azerbaijani and Russian.

History. People have lived in the region that is now Azerbaijan since prehistoric times. Medes invaded the region in the 700's B.C. Later invaders were Persians of the Achaemenid Empire in the 500's B.C. and Alexander the Great in the 300's B.C. Persians of the Sassanid dynasty controlled much of the region from the A.D. 200's until the 600's, when the Arabs conquered the area. The Arabs introduced Islam, the Muslim religion.

From the 1000's to the 1200's, Turkic tribes migrated into the region in large numbers and mixed with the Persians who lived there. These people became the ancestors of the Azerbaijanis. In the early 1500's, Azerbaijan fell to the Safavid Empire, which ruled Iran. The Ottoman Empire took control of Azerbaijan from the Safavids in the late 1500's but lost it to them again in the early 1600's.

In the early 1800's, Russia gained control of what is now Azerbaijan. Under Russia, industry, especially petroleum production, developed in Azerbaijan. By the late 1800's, Baku had become the world's leading producer of refined petroleum.

In 1917, revolutionaries known as Bolsheviks (later called Communists) seized control of the Russian government. In 1918, Azerbaijani nationalists set up an independent state in western Azerbaijan. But the Russians regained the area in 1920.

Soviet rule. In early 1922, Azerbaijan, Georgia, and Armenia combined to form the Transcaucasian Republic under Russia's leadership. Later that year, the Transcaucasian Republic joined Byelorussia (now Belarus), Russia, and Ukraine to form the Soviet Union. In 1936, the three parts of the Transcaucasian Republic became separate republics of the Soviet Union. Azerbaijan was called the Azerbaijan Soviet Socialist Republic.

The Soviet Union established a powerful central government and took control of Azerbaijan's industry and land. The Soviet Union *collectivized* agriculture in Azerbaijan—that is, it severely restricted private farming and transferred control of farms to the government. The Soviet rulers destroyed many Azerbaijani traditions, and they tried to reduce the influence of Islam. They closed down almost all mosques and religious schools in Azerbaijan. But the Soviets also built roads, schools, modern

housing, hospitals, and communication systems.

Independence. The Soviet government maintained strict control until the late 1980's. In 1989, Azerbaijan declared that its own laws overruled the laws of the Soviet Union. In August 1991, conservative Communist officials failed in an attempt to overthrow the Soviet president, Mikhail S. Gorbachev. During the upheaval that followed, Azerbaijan and several other republics of the Soviet Union declared their independence. In December, Azerbaijan joined other republics in a loose association called the Commonwealth of Independent States. The Soviet Union was formally dissolved on December 25.

In 1992, the Azerbaijani government slowly began to pass laws that encouraged a market economy. But most of the economy continued under government control. Most of the country's people remained very poor.

Dispute over Nagorno-Karabakh. An area known as Nagorno-Karabakh in southern Azerbaijan has been a source of dispute between Azerbaijan and neighboring Armenia. Most of its people are Armenians, and Armenia claims the area. In early 1988, Nagorno-Karabakh petitioned to become part of Armenia. This action triggered fighting between Azerbaijanis and Armenians for control of Nagorno-Karabakh. About 200,000 Azerbaijanis—almost all those who lived in Armenia—fled to Azerbaijan. About 250,000 Armenians fled Azerbaijan for Armenia. In 1994, the two countries declared a cease-fire. However, fighting continued from time to time, and the conflict over the territory remained unresolved.

Recent developments. In the middle and late 1990's, Azerbaijan made progress in selling government-owned farmland and businesses to private owners. It signed agreements with foreign oil companies for supplies of oil from the Caspian Sea. The agreements were expected to prove profitable for Azerbaijan. Nancy Lubin

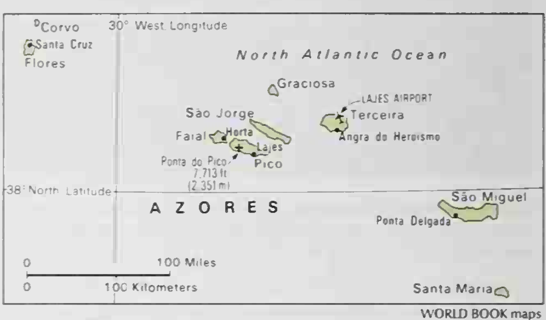
Azimuth, *AZ uh muhth,* is a measure along the horizon of the angle between an object and a reference point. The reference point is usually due north, and the angle is measured in a clockwise direction. An object that lies due east would have an azimuth of 90°. A wind of direction 270° is blowing from the west. Azimuth may also be measured from the south point. In this case, an object of azimuth 135° would lie to the northwest. The reference point can be made even clearer by giving the direction as S 135° W.



Surveyors use azimuth to help determine boundary points. Soldiers use it to direct artillery fire. Astronomers and navigators use it to locate objects in the sky. However, these people must also know the altitude to locate a star or other object in the sky. *Azimuth* once referred to objects in the sky, and *bearing* to land objects. But these terms now mean the same thing. Elizabeth Roemer

Azores, *AY zohrz* or *uh ZOHRZ,* are a group of nine islands that belong to Portugal. They are in the North Atlantic Ocean, about 800 miles (1,300 kilometers) west of Portugal. The Azores lie in the path of air and cable lines that link Europe and North America. The islands cover 868 square miles (2,247 square kilometers) and have a 320-mile (515-kilometer) coastline.

Approximately 248,000 people live in the Azores. Through the years, many Azoreans have immigrated to the United States. More people of Azorean descent live in the United States than live in the Azores. The most important city in the Azores is Ponta Delgada, which is on São Miguel Island.

The Azores are a group of islands in the North Atlantic Ocean. The islands, which belong to Portugal, lie about 800 miles (1,300 kilometers) west of the Portuguese mainland.

WORLD BOOK maps

The Azores form the peaks of a vast underwater volcanic mountain chain that extends through the mid-Atlantic Ocean from Iceland nearly to Antarctica. Earthquakes are fairly common in the Azores. Much of the land is hilly and wooded, but it produces corn, grapes, and citrus fruits.

Navigator Gonzalo Cabral claimed the Azores for Portugal in 1431. No one lived there at the time that Cabral arrived. However, the Portuguese soon colonized the islands. The United Kingdom used the Azores as a naval base in the warfare against Nazi submarines in World War II (1939-1945). Portugal, though neutral, permitted this because of an ancient treaty that allowed the United Kingdom to use the islands in time of war. The United States has military installations in the Azores.

During the mid-1970's, many Azoreans objected to Portugal's tight rule over the islands. Under the 1976 Portuguese Constitution and its later revisions, the Azores became an *autonomous* (self-governing) region of Portugal. However, some Azoreans continued to call for complete independence from Portugal.

Azov, *AZ awf* or *uh ZAWF,* **Sea of,** is a large, shallow inland sea bounded by Ukraine and Russia. It is connected with the Black Sea by the Kerch Strait. For location, see **Black Sea** (map).

The Sea of Azov covers about 14,500 square miles (37,550 square kilometers) and is only about 48 feet (15 meters) deep. Its western end is called the *Sivash,* or *Putrid Lake,* because of the many foul-smelling marshes and lagoons there. The lagoons yield important chemicals for industry. The Don River flows into the Gulf of Taganrog, which lies at the northeastern end of the sea. Ice and storms make shipping on the Sea of Azov dangerous in winter. Leslie Dienes

Detail of *Great City of Tenochtitlan* (1929-1945), a fresco mural by Diego Rivera, National Palace, Mexico City (Carlos Hernandez, Piramide Photo Service)

The Aztec Indians built a great civilization in Mexico before being conquered by the Spaniards in 1521. This painting shows the huge Aztec capital, Tenochtitlan, shortly before the Spanish conquest. Nobles, slaves, warriors, farmers, and traders crowd the busy market in the foreground.

Aztec

Aztec were an American Indian people who ruled a mighty empire in Mexico during the 1400's and early 1500's. The Aztec had one of the most advanced civilizations in the Americas. They built cities as large as any in Europe at that time. They also practiced a remarkable religion that affected every part of their lives. To worship their gods, the Aztec built towering temples, created huge sculptures, and held impressive ceremonies featuring bloody human sacrifices. Their empire was destroyed by the Spaniards, who conquered it in 1521. But the Aztec left a lasting mark on Mexican culture.

The name *Aztec* is also commonly applied to the people who founded the city of Tenochtitlan (pronounced *tay nohch TEE tlahn*). This city stood on the site of present-day Mexico City and, according to legend, was established in 1325. Its people referred to themselves by such names as *Colhua-Mexica, Mexica,* and *Tenochca.* In the 1400's, the city and its allies conquered many groups in central and southern Mexico, forming the Aztec empire. Tenochtitlan became the capital. *Aztec* also refers to this larger group of Indians who made up the empire. This article uses *Aztec* in that sense.

The Aztec empire

The center of Aztec civilization was the Valley of Mexico, a huge, oval basin about 7,500 feet (2,300 meters) above sea level. Although the valley was in the tropics, its high altitude gave it a mild climate. The surrounding lowlands had a hotter, wetter climate.

The Aztec empire included many cities and towns, especially in the Valley of Mexico. The largest city was the capital, Tenochtitlan, which occupied an island in Lake Texcoco. *Causeways* (raised earthen roads) linked the city to the mainland. On an island to the north stood the city of Tlatelolco, a huge commercial center. Both Tenochtitlan and Tlatelolco lay within the borders of what is now Mexico City. The present-day city covers much of the bed of Lake Texcoco, which was drained during the 1600's. In 1473, the people of Tenochtitlan conquered Tlatelolco and united the two cities. When the Spaniards arrived in the 1500's, Tenochtitlan may have had a population of 200,000 to 300,000. No Spanish city had so many people.

The emperor of the Aztec was called the *huey tlatoani* (great speaker). A council of high-ranking nobles chose him from the members of a royal family. The emperor had great power, but he had to consult the council of nobles before making important decisions. Military units were stationed in key locations throughout the empire to keep it secure. Most of these units were commanded by a great noble, who often also served as gov-

H. B. Nicholson, the contributor of this article, is Emeritus Professor of Anthropology at the University of California at Los Angeles.

ernor of the territory. An elaborate system of government offices administered the affairs of the empire. Many of the top positions were hereditary, but service to the emperor was the chief way for a person to obtain high office.

Aztec society had four main classes: (1) nobles, (2) commoners, (3) serfs, and (4) slaves. Among nobles and commoners, closely related families belonged to groups called *calpollis.* The members of a calpolli owned an area of land in common, and each family was allowed to farm a plot large enough for its needs. In addition to their calpolli land, most nobles had their own private land or received government land for use during their term in public office. Commoners made up the majority of the population, and many made a living by farming their calpolli plots. Serfs worked the land held by nobles and remained on the land when a new noble acquired it. Slaves were considered property, but their children were born free. Many slaves had been captured in war, and the Aztec also bought slaves from other groups. Other slaves were criminals or people who could not pay their debts.

Way of life

Religion was extremely important in Aztec life. The people devoted much of their time to religious practices and even waged war largely to obtain prisoners to sacrifice to their gods.

The Aztec worshiped hundreds of *divinities* (gods and goddesses), each of whom ruled one or more human activities or aspects of nature. The Aztec economy was based on farming, and so the people had many agricultural divinities. They include Centéotl, a corn god; Tláloc, a rain and fertility god; and Xipe Tótec, who was associated with springtime and regrowth. Other major gods included Tezcatlipoca, an all-powerful divinity; Tonatiuh, the sun god; Mictlantecuhtli, ruler of the dead; and Xiuhtecuhtli, the fire god. Huitzilopochtli, a war god, was the special guardian of the people of Tenochtitlan. The god Quetzalcóatl was associated with civilization and learning. However, he sometimes took the form of Ehécatl, god of the wind.

The Aztec held many religious ceremonies, the most important of which observed planting, harvesting, and other events in the agricultural year. The purpose of many of these ceremonies was to ensure good crops by winning the favor of the gods.

Human sacrifice played a vital role in the major ceremonies. Priests slashed open the chest of a living victim and tore out the heart. The Aztec believed that the gods needed human hearts and blood to remain strong. Worshipers sometimes ate portions of a victim's body. They may have thought that the dead person's strength and bravery passed to anyone who ate the flesh. Most victims were prisoners of war or slaves. But the Aztec also sacrificed children to the god Tláloc.

Most religious activities took place inside walled ceremonial centers. The chief structures within the centers were *teocallis.* The typical teocalli consisted of a solid base rising like giant stairsteps. A temple dedicated to a divinity stood at the top. Priests climbed a stairway on one side of the base to reach the temple. The ceremonial centers also included gardens, living quarters for the priests, sacred pools for ceremonial cleansing, and racks to hold the skulls of sacrificial victims. In addition, many centers had a playing court for a game that resembled basketball. The players tried to hit a rubber ball through a ring with their hips and knees. They could not use their hands or feet.

The Aztec had a 260-day religious calendar. Priests

The Aztec empire had its capital at Tenochtitlan, which stood on the site of present-day Mexico City. The empire was established during the 1400's, when the Aztec and their allies conquered much of central and southern Mexico.

Human sacrifice played a major role in Aztec religion. This drawing by an Aztec artist shows priests cutting out a victim's heart. Clay flutes broken during the ceremony lie nearby.

A statue of the goddess Coatlicue wears a necklace of human hands, hearts, and a skull. The goddess has been beheaded, and the snakes coming out of her neck represent streams of blood.

used the calendar to determine luck days for such activities as sowing crops, building houses, and going to war. The Aztec also had a 365-day solar calendar. It consisted of 18 months of 20 days each plus 5 extra days.

Every 52 years, the Aztec held a great celebration called the *Binding Up of the Years* or the *New Fire Ceremony.* Before the celebration, people let their hearth fires go out. At the start of the new 52-year cycle, the priests lit a new fire on the chest of a sacrificial victim. People pricked themselves to add their blood to the sacrifice. Then they relit their hearth fires from the new fire and feasted.

Family life. The typical Aztec household consisted of a husband and wife, their unmarried children, and a number of the husband's relatives. All members of this *extended family,* including the children, helped with the work. The husband's chief responsibility was to support the family, usually by farming or craftwork. The wife's duties included weaving the family's clothing and cooking their food.

Boys were educated by their father until about the age of 10. They then attended a school run by their calpolli or—especially if they belonged to the nobility— a school connected with a temple. Calpolli schools provided general education and military training. Temple schools offered a religious education, which prepared boys to become priests or other leaders. Some girls also attended the temple schools, but the majority learned household skills at home. The Aztec married at an early age, women at about 16 and men at about 20.

Food. The principal food of the Aztec was a thin cornmeal pancake called a *tlaxcalli.* In Spanish, it is called a *tortilla.* The Aztec used tlaxcallis to scoop up other foods, or they wrapped the tlaxcallis around bits of meat and vegetables to form *tacos.* Aztec cooking was rich and spicy. Many dishes had sauces flavored with chili peppers.

Hunting provided much of the meat in the Aztec diet. The chief game animals included deer, rabbits, and such birds as ducks and geese. The only animals raised for meat were dogs and turkeys.

The Aztec used the juice of *maguey* plants to make an alcoholic beverage called *octli.* Chocolate drink was also a favorite beverage, but only the wealthy could afford to have it often.

Clothing. Aztec women wore a loose, sleeveless blouse and a wraparound skirt. Men wore a cloth around their hips and a cloak knotted over one shoulder. The poorer people used cloth made from maguey fibers, but richer people had cotton clothing. The amount of decoration on a garment further indicated the wealth and social rank of the wearer.

Shelter. Most Aztec houses were simple and designed for usefulness rather than beauty. In the highlands, they were made of adobe. In the lowlands, the houses had thatched roofs, and the walls were made of branches or reeds plastered with clay. In addition to the main dwelling, most families had several other buildings, including a storehouse and a small sweat house, where the family took steam baths. Wealthy Aztec families had large adobe or stone houses built around a patio.

Arts and crafts. Aztec sculptures, which decorated temples and other buildings, were among the most elaborate in the Americas. The most famous surviving Aztec sculpture is the large, circular "Calendar Stone," which represents the Aztec universe. The stone measures about 12 feet (3.7 meters) in diameter. In its center is the face of the sun god Tonatiuh. Other carvings on

the stone represent the days of the Aztec month and religious symbols related to worship of the sun god. Many archaeologists believe that Aztec priests placed the hearts of human sacrifices on the stone.

The Aztec produced various forms of oral literature, including poetry and traditional accounts of their history. Music played a major part in religious services. The chief instruments were drums, flutes, and rattles.

Aztec craftworkers used feathers to make beautiful cloaks, headdresses, and other garments. Other important crafts included metalworking, pottery, weaving, and woodcarving.

Language. The Aztec spoke a language called *Náhuatl*. It belongs to a large group of Indian languages known as the Aztec-Tanoan or Uto-Aztecan family. This language family also includes the languages spoken by the Comanche, Pima, Shoshone, and other tribes of western North America.

The Aztec used a form of writing called *pictographic writing*, which consisted mostly of small pictures. Some pictures symbolized ideas. Others stood for the sounds of syllables. For example, the Aztec town of Coatepec was represented by a snake and a hill. The Náhuatl words for snake and hill were *coatl* and *tepetl*, which together sounded like Coatepec. The pictographic system of writing was not developed enough to provide full expression of ideas. The Aztec used it mainly for business records, censuses, historical and religious writings, and tax lists.

Warfare was considered a religious duty by the Aztec. They fought not only to enlarge their empire but also to take prisoners to sacrifice to the gods. The highest goal for a young man was to be a successful warrior. Men who took many captives in battle were rewarded. They received land, high social rank, and important government offices.

Aztec methods of combat were designed to capture prisoners rather than to kill. The chief weapon was a wooden club edged with sharp pieces of *obsidian* (volcanic glass). This weapon, called a *macuahuitl*, was effective for disabling an opponent without killing him. The Aztec also used bows and arrows and spears. A spear-throwing device called an *átlatl* increased the range and force of their spears. For protection, warriors carried shields and wore padded cotton armor.

Economy

Agriculture formed the basis of the Aztec economy. Corn was the most important crop. Farmers also grew avocados, beans, squashes, sweet potatoes, tomatoes, and many other crops. The lowlands provided such tropical products as cotton, papayas, rubber, and cacao beans, from which chocolate is made.

The basic agricultural tool was a pointed stick for digging. In the lowlands, which were covered with dense forest, farmers practiced *slash-and-burn agriculture*. They chopped down and burned a section of forest, then planted crops in the clearing. The ashes fertilized the soil. In the highlands, the Aztec cut terraces into the hillsides to increase the amount of level farmland. They also dug irrigation systems to water their crops. In addition, farmers turned areas of shallow lakes into cropland by scooping up mud from the lake bottoms to form islands. These islands were called *chinampas*. The farmers regularly added fresh mud, which was extremely fertile. As a result, the chinampas yielded huge crops. Lake Xochimilco in Mexico City still has many chinampas. Although they do not float, they are often called *floating gardens*.

Trade and transportation. The market place was a major center of Aztec life. The market at Tlatelolco was the largest in the Americas. It displayed nearly every

kind of merchandise available in the Aztec world. The Spanish explorer Hernando Cortés reported that more than 60,000 persons visited it daily. There were also many smaller markets throughout the empire. Government officials supervised the trading.

Merchants called *pochteca* traveled throughout the empire on trading expeditions. The merchants employed many bearers, who marched in long caravans with heavy loads on their backs. People of the lowlands traded such products as cacao beans, cotton, jaguar pelts, rubber, and the feathers of tropical birds. In return, they received goods from the highlands, including obsidian, which was used for knives, and a variety of manufactured products.

The Aztec had no system of money as we know it. They usually traded goods and services for other goods and services. But the Aztec used cacao beans and other widely acceptable goods somewhat as we use money.

The Aztec used the wheel only in toys, and they had no beasts of burden. As a result, the people themselves carried all their goods on land. Dugout canoes were an important means of transportation in the Valley of Mexico, where lakes, canals, and other waterways covered much of the area.

History

The Aztec migration. According to Aztec legend, the ancestors of the people who founded Tenochtitlan came to the Valley of Mexico from a place in the north called *Aztlan.* The name *Aztec* comes from *Aztlan.* The Aztec wandered for many years before settling in the valley in the 1200's. At first, they were subjects of people who lived in the area. But later—in 1325, according to legend—they founded their own city, Tenochtitlan.

Growth of the Aztec empire. By the early 1400's, Tenochtitlan had become a powerful city that controlled the region around it, forming a kind of city-state. Tenochtitlan joined with Texcoco and Tlacopan, two other city-states in the Valley of Mexico, to form an alliance. Tenochtitlan became the most powerful member of the alliance and began to build what became the Aztec empire. Under Montezuma I, who ruled from 1440 to 1469, the alliance conquered large areas to the east and south. Montezuma's name is also spelled *Moctezuma* or *Motecuhzoma.* His successors expanded the empire until it extended between what are now Guatemala and the Mexican state of San Luis Potosí. Hundreds of conquered towns paid heavy taxes in goods to the empire. When Montezuma II became emperor in 1502, the Aztec empire was at the height of its power.

The Spanish conquest. In 1519, the Spanish explorer Hernando Cortés landed on the east coast of Mexico and marched inland to the Aztec capital. He and his troops were joined by many Indians who had been conquered by the Aztec and resented their heavy taxes. Montezuma II did not oppose the advancing Spaniards, possibly because he thought Cortés represented the god Quetzalcóatl. An Aztec legend said that Quetzalcóatl had sailed across the sea and would return someday. Cortés entered Tenochtitlan and made Montezuma a prisoner.

In 1520, the Aztec rebelled and drove the Spaniards from the city. Montezuma died from wounds received in the fighting. Cortés reorganized his army and began a bloody attack on Tenochtitlan in May 1521. Montezuma's successor, Cuauhtémoc, surrendered in August the same year.

The Aztec heritage. Little Aztec architecture remains. The Spaniards considered it their duty as Christians to wipe out the temples and all other traces of the Aztec religion. They destroyed Tenochtitlan and built Mexico City on the ruins. However, archaeologists have

Drawing by an unknown Aztec artist from *Historia de las Indias de Nueva España e Islas de Tierra Firme* (mid-1500's) by Diego Duran. Biblioteca Nacional, Madrid, Spain (Ampliaciones y Reproducciones MAS)

The Spanish conquest in 1521 destroyed the Aztec empire. This drawing shows Aztec warriors, *right,* fighting to recapture a palace from the Spaniards, *left.* One Aztec wears an eagle costume, and one a jaguar suit. Warriors earned the right to wear such costumes by taking many prisoners.

An Aztec pyramid stands at Santa Cecilia, Mexico, near Mexico City. Priests climbed the stairway to offer sacrifices in front of the temple at the top. The Mexican government has rebuilt the temple, which was damaged by the Spaniards.

excavated the site of the Great Temple in downtown Mexico City. They have uncovered all four sides of the building and recovered about 6,000 objects, including jewelry, pottery, statues, wall carvings, and remains of animal and human sacrifices. Archaeologists have restored some other Aztec buildings, including temples at Tenayuca and Tepoztlan near Mexico City. In addition, the National Museum of Anthropology in Mexico City has a large collection of Aztec art.

Thousands of people in Mexico have Aztec ancestors, and many of them speak a modern form of Náhuatl. Many Mexican place names, including *Acapulco* and *Mexico* itself, come from Náhuatl, as do the English words *avocado, chocolate,* and *tomato.* Such Mexican painters as José Orozco, Diego Rivera, and David Siqueiros have used Aztec themes in their work. Foods of Aztec origin, including chili, chocolate, and tacos, have become popular in many countries.

Descendants of the Aztec also live in the United States, especially in California and Texas. During the mid-1900's, these Mexican Americans developed a new cultural pride in their Aztec ancestry, which they called the *heritage of Aztlan.* H. B. Nicholson

Questions

Why did Montezuma II fail to oppose Cortés?
Why did the Aztec want prisoners of war?
When was the Aztec empire at its height?
What were *chinampas?*
How did the Aztec move their goods on land?
Why did the Aztec think human sacrifices were necessary?
What are two popular foods of Aztec origin?
Where was the Aztec capital of Tenochtitlan?
Why are so few Aztec buildings left?

Aztec Ruins National Monument lies in northwestern New Mexico. It contains ruins of a Pueblo Indian town of the 1100's, including a 500-room dwelling place. The ruins were misnamed Aztec by American settlers of the 1800's. The monument was established in 1923. For its area, see National Park System (table: National monuments). Critically reviewed by the National Park Service

Azurite, *AZH uh ryt,* is a blue mineral that contains copper. Azurite is mined as a copper ore, but most azurite is used for ornamentation. Small stones are polished and mounted in jewelry. Slabs are shaped into decorative objects such as bowls. Artists once used ground azurite as a pigment for paint. Azurite's chemical formula is $Cu_3(CO_3)_2(OH)_2$. Its crystal structure is *monoclinic* (see Crystal [Classifying crystals]). Azurite is found throughout the world, usually in the same location as *malachite,* a similar mineral that is green. But the best crystals come from Chessy, near Lyon, France. Fine azurite also occurs in Australia, Greece, Mexico, Namibia, Romania, Russia, and the United States. Kenneth J. De Nault
